

# Open Geospatial Consortium, Inc.

Date: 2004-02-07

Reference number of this OpenGIS® project document: **OGC 03-105r1**

Version: 3.1.1

Category: OpenGIS® Recommendation Paper

Editors: Simon Cox, Paul Daisey, Ron Lake, Clemens Portele, Arliss Whiteside

## **OpenGIS® Geography Markup Language (GML) Implementation Specification**

**Notice: This 3.1.1 document is the same as version 3.1.0. The only changes are bug fixes in the online schemas.**

Document type: OpenGIS® Recommendation Paper  
Document subtype: -  
Document stage: Final  
Document language: English

## Copyright notice

Copyright 1999, 2000, 2001, 2002, 2003, 2004 Open GIS Consortium, Inc.

The companies listed above have granted the Open GIS Consortium, Inc. (OGC) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version.

This document does not represent a commitment to implement any portion of this specification in any company's products.

OGC's Legal, IPR and Copyright Statements are found at <http://www.opengis.org/about/?page=ipr&view=ipr>

### NOTICE

Permission to use, copy, and distribute this document in any medium for any purpose and without fee or royalty is hereby granted, provided that you include the above list of copyright holders and the entire text of this NOTICE.

We request that authorship attribution be provided in any software, documents, or other items or products that you create pursuant to the implementation of the contents of this document, or any portion thereof.

No right to create modifications or derivatives of OGC documents is granted pursuant to this license. However, if additional requirements (as documented in the Copyright FAQ at [http://www.opengis.org/about/?page=ipr&view=ipr\\_faq](http://www.opengis.org/about/?page=ipr&view=ipr_faq)) are satisfied, the right to create modifications or derivatives is sometimes granted by the OGC to individuals complying with those requirements.

THIS DOCUMENT IS PROVIDED "AS IS," AND COPYRIGHT HOLDERS MAKE NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, NON-INFRINGEMENT, OR TITLE; THAT THE CONTENTS OF THE DOCUMENT ARE SUITABLE FOR ANY PURPOSE; NOR THAT THE IMPLEMENTATION OF SUCH CONTENTS WILL NOT INFRINGE ANY THIRD PARTY PATENTS, COPYRIGHTS, TRADEMARKS OR OTHER RIGHTS.

COPYRIGHT HOLDERS WILL NOT BE LIABLE FOR ANY DIRECT, INDIRECT, SPECIAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF ANY USE OF THE DOCUMENT OR THE PERFORMANCE OR IMPLEMENTATION OF THE CONTENTS THEREOF.

The name and trademarks of copyright holders may NOT be used in advertising or publicity pertaining to this document or its contents without specific, written prior permission. Title to copyright in this document will at all times remain with copyright holders.

RESTRICTED RIGHTS LEGEND. Use, duplication, or disclosure by government is subject to restrictions as set forth in subdivision (c)(1)(ii) of the Right in Technical Data and Computer Software Clause at DFARS 252.227.7013

### Warning

This document is not an OGC Standard. It is distributed for review and comment. It is subject to change without notice and may not be referred to as an OGC Standard.

Recipients of this document are invited to submit, with their comments, notification of any relevant patent rights of which they are aware and to provide supporting documentation. Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. Open GIS Consortium shall not be held responsible for identifying any or all such patent rights. However, to date, no such rights have been claimed or identified.

## Contents

1	Scope.....	1
2	Conformance .....	1
3	Normative references .....	2
4	Terms and definitions.....	3
5	Conventions .....	9
5.1	Deprecated parts of previous versions of GML .....	9
5.2	Symbols (and abbreviated terms) .....	9
5.3	UML Notation.....	10
5.4	XML Schema.....	11
6	Overview of GML Schemas.....	11
6.1	Review of GML version 2 – XML for Simple Features .....	11
6.2	GML version 3 – more than Simple Features, plus ISO conformance .....	11
6.3	Backward compatibility .....	12
6.4	GML 3 Application Schemas.....	12
6.5	How GML 3 components are factored into schema documents .....	12
6.6	GML schemas to import into your GML 3 Application Schema .....	14
7	GML schemas – general rules and base schemas .....	15
7.1	Introduction, namespaces, versioning .....	15
7.2	Xlinks – Object Associations and Remote Properties .....	15
7.3	Basic Types .....	15
7.3.1	Overview .....	15
7.3.2	Convenience types .....	16
7.3.2.1	gml:NullType.....	16
7.3.2.2	gml:Null .....	17
7.3.2.3	gml:SignType.....	17
7.3.3	Simple content .....	18
7.3.3.1	gml:booleanOrNull, gml:doubleOrNull, gml:integerOrNull, gml:NameOrNull, gml:stringOrNull .....	18
7.3.3.2	gml:CodeType.....	18
7.3.3.3	gml:MeasureType.....	19
7.3.4	Lists .....	19
7.3.4.1	gml:booleanList, gml:doubleList, gml:integerList, gml:NameList, gml:NCNameList, gml:QNameList, gml:booleanOrNullList, gml:NameOrNullList, gml:doubleOrNullList, gml:integerOrNullList .....	19
7.3.4.2	gml:CodeListType, gml:CodeOrNullListType.....	20
7.3.4.3	gml:MeasureListType, gml:MeasureOrNullListType .....	21
7.4	GML model and syntax.....	21
7.4.1	GML instance documents .....	21
7.4.2	Lexical conventions.....	22
7.4.3	XML schema definition of GML languages.....	22
7.5	gmlBase schema .....	23
7.5.1	Goals of base schema .....	23
7.5.2	Base objects .....	23
7.5.2.1	gml:_Object.....	23
7.5.2.2	gml:_GML, gml:AbstractGMLType .....	23
7.5.3	GML properties.....	24
7.5.3.1	gml:_association, gml:AssociationType.....	24

7.5.3.2	<code>gml:AssociationAttributeGroup</code> .....	25
7.5.4	By value or by reference? .....	25
7.5.4.1	<code>gml:_strictAssociation</code> .....	26
7.5.4.2	<code>gml:_reference</code> , <code>gml:ReferenceType</code> .....	26
7.5.5	Convenience properties and property types.....	27
7.5.5.1	<code>gml:member</code> .....	27
7.5.5.2	<code>gml:stringOrRefType</code> .....	27
7.5.6	Standard properties of GML Objects .....	27
7.5.6.1	<code>gml:metaDataProperty</code> .....	28
7.5.6.2	<code>gml:description</code> .....	28
7.5.6.3	<code>gml:name</code> .....	28
7.5.6.4	<code>gml:StandardObjectProperties</code> .....	28
7.5.6.5	<code>gml:id</code> .....	28
7.5.7	Bags and arrays .....	29
7.5.7.1	<code>gml:ArrayAssociationType</code> .....	29
7.5.7.2	<code>gml:Array</code> , <code>gml:ArrayType</code> , <code>gml:Bag</code> , <code>gml:BagType</code> .....	29
7.5.8	Metadata.....	30
7.5.8.1	<code>gml:metaDataProperty</code> , <code>gml:metaDataPropertyType</code> , <code>gml:_MetaData</code> , <code>gml:AbstractMetaDataType</code> .....	30
7.5.8.2	<i><code>gml:GenericMetaData</code></i> , <i><code>gml:GenericMetaDataType</code></i> .....	31
8	GML schemas – feature model .....	31
8.1	General Concepts .....	31
8.2	Feature schema.....	31
8.2.1	Features .....	32
8.2.1.1	<code>gml:AbstractFeatureType</code> .....	32
8.2.1.2	<code>gml:_Feature</code> .....	32
8.2.2	Standard feature properties .....	33
8.2.2.1	<code>gml:boundedBy</code> , <code>gml:BoundingShapeType</code> , <code>gml:EnvelopeWithTimePeriod</code> , <code>gml:EnvelopeWithTimePeriodType</code> .....	33
8.2.2.2	<code>gml:location</code> , <code>gml:LocationPropertyType</code> , <code>gml:LocationKeyword</code> , <code>gml:LocationString</code> .....	33
8.2.2.3	<i><code>gml:priorityLocation</code></i> , <i><code>gml:priorityLocationType</code></i> .....	34
8.2.2.4	<code>gml:featureProperty</code> , <code>gml:FeaturePropertyType</code> , <code>gml:featureMember</code> .....	35
8.2.2.5	<code>gml:featureMembers</code> , <code>gml:FeatureArrayTypePropertyType</code> .....	35
8.2.3	Geometry Properties.....	35
8.2.4	Topology Properties .....	37
8.2.5	Temporal Properties .....	38
8.2.5.1	General purpose temporal properties .....	38
8.2.5.2	Specific temporal properties .....	38
8.2.6	Defining specific feature types .....	39
8.2.6.1	<code>gml:BoundedFeatureType</code> .....	39
8.2.7	Feature Collections.....	40
8.2.7.1	<code>gml:AbstractFeatureCollectionType</code> .....	40
8.2.7.2	<code>gml:_FeatureCollection</code> , <code>gml:FeatureCollection</code> , <code>gml:FeatureCollectionType</code> .....	40
8.3	Spatial reference system used in a feature or feature collection .....	41
9	GML schemas – basic geometry .....	41
9.1	General Concepts .....	41
9.1.1	Overview .....	41
9.1.2	Abstract Geometry.....	42
9.1.2.1	<code>gml:AbstractGeometryType</code> .....	42
9.1.2.2	<code>SRSReferenceGroup</code> .....	42
9.1.2.3	<code>SRSInformationGroup</code> .....	43
9.1.2.4	<code>gml:_Geometry</code> .....	43
9.1.2.5	<code>gml:GeometryPropertyType</code> .....	43
9.1.2.6	<code>gml:GeometryArrayTypePropertyType</code> .....	44
9.1.3	Coordinate Geometry .....	44

9.1.3.1	gml:DirectPositionType, gml:pos .....	44
9.1.3.2	gml:DirectPositionListType, gml:posList .....	44
9.1.3.3	gml:geometricPositionGroup .....	45
9.1.3.4	gml:geometricPositionListGroup .....	45
9.1.3.5	gml:CoordinatesType, gml:coordinates .....	45
9.1.3.6	<i>gml:CoordType, gml:coord</i> .....	46
9.1.4	Vectors .....	46
9.1.4.1	gml:VectorType, gml:Vector .....	46
9.1.5	Envelopes .....	47
9.1.5.1	gml:EnvelopeType, gml:Envelope .....	47
9.2	Geometric Primitives .....	47
9.2.1	Simple Geometric Primitives (0- and 1-dimensional).....	47
9.2.1.1	gml:AbstractGeometricPrimitiveType, gml:_GeometricPrimitive .....	47
9.2.1.2	gml:PointType, gml:Point .....	48
9.2.1.3	gml:PointPropertyType, gml:pointProperty .....	48
9.2.1.4	gml:PointArrayPropertyType, gml:pointArrayProperty .....	49
9.2.1.5	gml:AbstractCurveType, gml:_Curve .....	49
9.2.1.6	gml:CurvePropertyType, gml:curveProperty .....	49
9.2.1.7	gml:CurveArrayPropertyType, gml:curveArrayProperty .....	50
9.2.1.8	gml:LineStringType, gml:LineString .....	50
9.2.1.9	<i>gml:LineStringPropertyType, gml:lineStringProperty</i> .....	51
9.2.2	Simple Geometric Primitives (2-dimensional).....	51
9.2.2.1	gml:AbstractSurfaceType, gml:_Surface .....	51
9.2.2.2	gml:SurfacePropertyType, gml:surfaceProperty .....	51
9.2.2.3	gml:SurfaceArrayPropertyType, gml:surfaceArrayProperty .....	52
9.2.2.4	gml:PolygonType, gml:Polygon .....	52
9.2.2.5	gml:exterior, gml:interior, gml:outerBoundaryIs, gml:InnerBoundaryIs.....	52
9.2.2.6	gml:AbstractRingType, gml:_Ring .....	53
9.2.2.7	gml:AbstractRingPropertyType .....	53
9.2.2.8	gml:LinearRingType, gml:LinearRing .....	53
9.2.2.9	gml:LinearRingPropertyType .....	54
9.2.2.10	<i>gml:PolygonPropertyType, gml:polygonProperty</i> .....	54
10	GML schemas – more geometric primitives.....	54
10.1	Overview .....	54
10.2	Additional geometric primitives .....	55
10.2.1	1-dimensional geometric primitives.....	55
10.2.1.1	gml:CurveType, gml:Curve.....	55
10.2.1.2	gml:AbstractCurveSegmentType, gml:_CurveSegment .....	55
10.2.1.3	gml:CurveSegmentArrayPropertyType, gml:segments .....	56
10.2.1.4	gml:CurveInterpolationType.....	56
10.2.1.5	gml:LineStringSegmentType, gml:LineStringSegment.....	56
10.2.1.6	gml:ArcStringType, gml:ArcString .....	57
10.2.1.7	gml:ArcType, gml:Arc .....	58
10.2.1.8	gml:CircleType, gml:Circle.....	59
10.2.1.9	gml:ArcStringByBulgeType, gml:ArcStringByBulge.....	59
10.2.1.10	gml:ArcByBulgeType, gml:ArcByBulge.....	60
10.2.1.11	gml:ArcByCenterPointType, gml:ArcByCenterPoint.....	61
10.2.1.12	gml:CircleByCenterPointType, gml:CircleByCenterPoint.....	62
10.2.1.13	gml:CubicSplineType, gml:CubicSpline .....	62
10.2.1.14	gml:BSplineType, gml:BSpline .....	64
10.2.1.15	gml:KnotType, gml:KnotPropertyType .....	65
10.2.1.16	gml:KnotTypesType .....	65
10.2.1.17	gml:BezierType, gml:Bezier .....	65
10.2.1.18	gml:OrientableCurveType, gml:OrientableCurve, gml:baseCurve .....	66
10.2.1.19	gml:OffsetCurveType, gml:OffsetCurve.....	67
10.2.1.20	gml:AffinePlacementType, gml:AffinePlacement .....	68
10.2.1.21	gml:ClothoidType, gml:Clothoid.....	68

10.2.1.22	<b>gml:GeodesicStringType, gml:GeodesicSting</b> .....	69
10.2.1.23	<b>gml:GeodesicType, gml:Geodesic</b> .....	70
10.2.2	<b>2-dimensional geometric primitives</b> .....	70
10.2.2.1	<b>gml:SurfaceType, gml:Surface</b> .....	70
10.2.2.2	<b>gml:AbstractSurfacePatchType, gml :_SurfacePatch</b> .....	70
10.2.2.3	<b>gml:SurfacePatchArrayPropertyType, gml:patches</b> .....	71
10.2.2.4	<b>gml:SurfaceInterpolationType</b> .....	71
10.2.2.5	<b>gml:PolygonPatchType</b> .....	71
10.2.2.6	<b>gml:TriangleType, gml:Triangle</b> .....	72
10.2.2.7	<b>gml:RectangleType, gml:Rectangle</b> .....	72
10.2.2.8	<b>gml:RingType</b> .....	72
10.2.2.9	<b>gml:RingPropertyType</b> .....	73
10.2.2.10	<b>gml:OrientableSurfaceType, gml:OrientableSurface, gml:baseSurface</b> .....	73

## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

Attention is drawn to the possibility that some of the elements of this International Standard may be the subject of patent rights. Open GIS Consortium Inc. and ISO shall not be held responsible for identifying any or all such patent rights.

International Standard ISO 19136 was prepared by the Technical Committee of the Open GIS Consortium and Technical Committee ISO/TC 211, *Geographic information/Geomatics*.

This edition of GML supersedes version 3.0.0 (OGC document 02-023r4).

GML is a living standard, originally developed within the Open GIS Consortium (OGC). This ISO/TC 211 Committee Draft is targeted to become GML version 3.1 within OGC. As GML is already used in several commercial data and software products worldwide, compatibility of this version with previous versions of GML is important. OGC has decided that the best way to introduce changes to existing structures within GML is to deprecate elements, types, attributes and groups that shall not be used in new applications. These deprecated structures will then be removed from GML in a future version – depending on the adoption of these changes by the market.

Member bodies and liaisons are invited to address in their comments the issue whether this International Standard should contain the deprecated structures, too, or if they should be removed from the standard. In the latter case, ISO 19136 would be a profile of the GML Implementation Specification according to the rules of this standard.

## Introduction

Geography Markup Language is an XML grammar written in XML Schema for the modelling, transport, and storage of geographic information.

The key concepts used by Geography Markup Language (GML) to model the world are drawn from the OpenGIS<sup>®</sup> Abstract Specification and the ISO 19100 series.

GML provides a variety of kinds of objects for describing geography including features, coordinate reference systems, geometry, topology, time, units of measure and generalized values.

A geographic feature is "an abstraction of a real world phenomenon; it is a geographic feature if it is associated with a location relative to the Earth". So a digital representation of the real world can be thought of as a set of features. The state of a feature is defined by a set of properties, where each property can be thought of as a {name, type, value} triple.

The number of properties a feature may have, together with their names and types, are determined by its type definition. Geographic features with geometry are those with properties that may be geometry-valued. A feature collection is a collection of features that can itself be regarded as a feature; as a consequence a feature collection has a feature type and thus may have distinct properties of its own, in addition to the features it contains.

Geographic features in GML include coverages and observations as subtypes.

A coverage is a sub-type of feature that has a coverage function with a spatial domain and a value set range of homogeneous 2 to n dimensional tuples. A coverage can represent one feature or a collection of features "to model and make visible spatial relationships between, and the spatial distribution of, earth phenomena."

An observation models the act of observing, often with a camera, a person or some form of instrument ("an act of recognizing and noting a fact or occurrence often involving measurement with instruments"). An observation is considered to be a GML feature with a time at which the observation took place, and with a value for the observation.

A reference system provides a scale of measurement for assigning values "to a location, time or other descriptive quantity or quality".

A coordinate reference system consists of a set of coordinate system axes that is related to the earth through a datum that defines the size and shape of the earth. Geometries in GML indicate the coordinate reference system in which their measurements have been made. The "parent" geometry element of a geometric complex or geometric aggregate makes this indication for its constituent geometries.

A temporal reference system provides standard units for measuring time and describing temporal length or duration. Following ISO 8601, the Gregorian calendar with UTC is used in GML as the default temporal reference system.

A Units of Measure (UOM) dictionary provides definitions of numerical measures of physical quantities, such as length, temperature, and pressure, and of conversions between UOMs.

# OpenGIS<sup>®</sup> Geography Markup Language (GML) Implementation Specification – Version 3.1.0

## 1 Scope

The Geography Markup Language (GML) is an XML encoding in compliance with ISO 19118 for the transport and storage of geographic information modelled according to the conceptual modelling framework used in the ISO 19100 series and including both the spatial and non-spatial properties of geographic features.

This specification defines the XML Schema syntax, mechanisms, and conventions that:

- Provide an open, vendor-neutral framework for the definition of geospatial application schemas and objects;
- Allow profiles that support proper subsets of GML framework descriptive capabilities;
- Support the description of geospatial application schemas for specialized domains and information communities;
- Enable the creation and maintenance of linked geographic application schemas and datasets;
- Support the storage and transport of application schemas and data sets;
- Increase the ability of organizations to share geographic application schemas and the information they describe.

Implementers may decide to store geographic application schemas and information in GML, or they may decide to convert from some other storage format on demand and use GML only for schema and data transport.

**NOTE** The model is conformant with the parts of the Abstract Specification of OGC and the ISO 19100 series which are listed in the normative references. For other parts of this specifications no abstract specification was available.

## 2 Conformance

Conformance with this specification shall be checked using all the relevant tests specified in Annex A (normative). The framework, concepts, and methodology for testing, and the criteria to be achieved to claim conformance are specified in ISO 19105: Geographic information — Conformance and Testing.

In order to conform to this OpenGIS<sup>®</sup> Implementation Specification, a software implementation shall choose to implement:

- a) Any one of the conformance levels specified in Annex B (normative).

### 3 Normative references

NOTE Due to differences with the current version of ISO 19111 (Geographic Information – Spatial referencing by coordinates) this standard is currently not in the list of normative references. See annex D.

## 4 Terms and definitions

### 4.1

#### **application schema**

conceptual schema for data required by one or more applications [ISO 19101]

### 4.2

#### **GML application schema**

an XML Schema written according to the GML rules for application schemas and which defines a vocabulary of geographic objects for a particular domain of discourse

### 4.3

#### **association**

semantic relationship between two or more classifiers that specifies connections among their instances [ISO 19103]

### 4.4

#### **attribute <XML>**

an information item in the XML Information Set [Infoset]

NOTE 1 In this document an attribute is an XML attribute unless otherwise specified. The syntax of an XML attribute is "Attribute::= Name = AttValue". An attribute typically acts as an XML element modifier (e.g. <Road gml:id = "r1" /> here gml:id is an attribute.

NOTE 2 ISO 19130 defines the term "attribute" as: property which describes a geometrical, topological, thematic, or other characteristic of an entity. This definition is wider than the term "attribute" as it is used in this International Standard and corresponds more to a "GML property".

### 4.5

#### **boundary**

**set** that represents the limit of an entity [ISO 19107]

### 4.6

#### **category**

One of a set of classes in a classification scheme.

### 4.7

#### **child <XML>**

an XML element c that is in the content of another element p, its parent, but is not in the content of any other element in the content of p

**4.8****closure**

union of the **interior** and **boundary** of a **topological** or **geometric object** [ISO 19107]

**4.9****codelist**

Value domain including a code for each permissible value

**4.10****codespace**

Rule or authority for a code, name, term or category

EXAMPLE Examples of a codespace include dictionaries, authorities, codelists, etc.

**4.11****composite curve**

**sequence** of **curves** such that each curve (except the first) starts at the end point of the previous curve in the **sequence** [ISO 19107]

NOTE A composite curve, as a set of direct positions, has all the properties of a curve.

**4.12****composite solid**

connected **set** of **solids** adjoining one another along shared **boundary surfaces** [ISO 19107]

NOTE A composite solid, as a set of direct positions, has all the properties of a solid.

**4.13****composite surface**

connected **set** of **surfaces** adjoining one another along shared **boundary curves** [ISO 19107]

NOTE A composite surface, as a set of direct positions, has all the properties of a surface.

**4.14****control point**

one of a sequence of points defining the position of a curve segment or surface patch – together with additional information about the interpolation method

NOTE The controlPoints of a curve segment are used to control its shape, but are not always on the curve segment itself.

**4.15****coordinate**

one of a **sequence** of numbers designating the position of a **point** in n-dimensional space [ISO 19111]

NOTE In a coordinate reference system, the n numbers shall be qualified by units.

**4.16****coordinate reference system**

**coordinate system** that is related to the real world by a datum [ISO 19111]

**4.17****coordinate system**

set of mathematical rules for specifying how **coordinates** are to be assigned to **points** [ISO 19111]

**4.18****coordinate tuple**

**tuple** composed of coordinates

#### 4.19

##### **coverage**

feature that acts as a function to return values from its range for any direct position within its spatiotemporal domain [ISO 19123]

#### 4.20

##### **curve**

1-dimensional **geometric primitive**, representing the continuous image of a line

NOTE The boundary of a curve is the set of points at either end of the curve. If the curve is a cycle, the two ends are identical, and the curve (if topologically closed) is considered to not have a boundary. The first point is called the start point, and the last is the end point. Connectivity of the curve is guaranteed by the "continuous image of a line" clause. A topological theorem states that a continuous image of a connected set is connected.

#### 4.21

##### **data type**

specification of a value domain with operations allowed on values in this domain [ISO 19103]

EXAMPLE Integer, Real, Boolean, String, Date (conversion of a data into a series of codes).

NOTE Data types include primitive predefined types and user-definable types.

#### 4.22

##### **datum**

parameter or set of parameters that serve as a reference or basis for the calculation of other parameters [ISO 19111]

NOTE 1 A datum defines the position of the origin, the scale, and the orientation of the axes of a coordinate system.

NOTE 2 A datum may be a geodetic datum, a vertical datum or an engineering datum.

#### 4.23

##### **direct position**

position described by a single set of coordinates within a coordinate reference system [ISO 19107]

#### 4.24

##### **domain**

well-defined **set** [ISO 19103]

NOTE 1 A mathematical **function** can be defined on this set, i.e. in a function  $f:A \rightarrow B$   $A$  is the domain of the function  $f$ .

NOTE 2 A domain as in domain of discourse refers to a subject or area of interest.

#### 4.25

##### **edge**

1-dimensional topological primitive [ISO 19107]

#### 4.26

##### **element <XML>**

an information item in the XML information Set

NOTE From the XML Information Set Specification: Each XML document contains one or more elements, the boundaries of which are either delimited by start-tags and end-tags, or, for empty elements, by an empty-element tag. Each element has a type, identified by name, sometimes called its "generic identifier" (GI), and may have a set of attribute specifications. Each attribute specification has a name and a value.

#### 4.27

##### **exterior**

difference between the universe and the **closure** [ISO 19107]

**4.28****face**

2-dimensional **topological primitive** [ISO 19107]

NOTE The geometric realization of a face is a surface. The boundary of a face is the set of directed edges within the same topological complex that are associated to the face via the boundary relations. These can be organized as rings

**4.29****feature**

abstraction of real world phenomena [ISO 19101]

NOTE A feature may occur as a type or an instance. Feature type or feature instance should be used when only one is meant

**4.30****feature relationship**

**association** between **features** [ISO 19103]

**4.31****function**

**rule that associates each element from a domain (source, or domain of the function) to a unique element in another domain (target, co-domain, or range) [ISO 19107]**

**geodetic datum**

datum describing the relationship of a coordinate system to the Earth [ISO 19111]

NOTE In most cases, the geodetic datum includes an ellipsoid definition.

**4.33****geometric object**

spatial object representing a geometric set [ISO 19107]

**4.34****geometric set**

set of direct positions [ISO 19107]

**4.35****geometry property <GML>**

**Property** of a GML feature that describes some aspect of the geometry of the feature.

NOTE The geometry property name is the role of the geometry in relation to the feature.

**4.36****grid**

network composed of two or more sets of **curves** in which the members of each set intersect the members of the other sets in an algorithmic way [ISO 19123]

NOTE The curves partition a space into grid cells.

**4.37****interior**

**set of all direct positions** that are on a **geometric object** but which are not on its **boundary** [ISO 19107]

**4.38****line string**

curve composed of straight-line segments

**4.39****measure <GML>**

A value described using a numeric amount with a scale or using a scalar reference system

NOTE When used as a noun, measure is a synonym for quantity.

**4.40  
measurand**

Phenomenon or property that is subject to observation.

**4.41  
namespace <XML>**

Collection of names, identified by an URI reference which are used in XML documents as element names and attribute names [XML]

**4.42  
node**

0-d topological primitive [ISO 19107]

**4.43  
object**

entity with a well defined boundary and identity that encapsulates state and behaviour [ISO 19107]

NOTE A GML object is an XML element of a type derived from AbstractGMLType.

**4.44  
observable**

Phenomenon or property that is subject to observation

**4.45  
point**

0-dimensional **geometric primitive**, representing a position [ISO 19107]

NOTE The boundary of a point is the empty set.

**4.46  
polygon**

a planar **surface** defined by 1 exterior boundary and 0 or more interior boundaries

**4.47  
property <GML>**

a child element of a GML object.

NOTE It corresponds to feature attribute and feature association in ISO 19109. If a GML **property of a feature** has an xlink:href attribute that references a feature, the **property** represents a feature association.

**4.48  
quantity**

property ascribed to phenomena, bodies or substances that can be used to specify the size, amount, or extent of a particular phenomenon, body or substance [ISO 19126]

NOTE In GML a quantity is always a value described using a numeric amount with a scale or using a scalar reference system. Quantity is a synonym for measure when the latter is used as a noun.

**4.49  
range**

the set B of a mathematical function ( $f:A \rightarrow B$ ) is called the range of the function.

**4.50  
rectified grid**

**grid** for which there is an affine transformation between the grid coordinates and the **coordinates** of an external **coordinate reference system** [ISO 19123]

**4.51****schema**

formal description of a model [ISO 19101]

**NOTE** In general, a schema is an abstract representation of an **object's** characteristics and relationship to other **objects**. An XML schema represents the relationship between the attributes and elements of an XML object (for example, a document or a portion of a document)

**4.52****semantic type**

A category of objects that share some common characteristics and are thus given an identifying type name in a particular domain of discourse.

**4.53****sequence**

finite, ordered collection of related items (objects or values) that may be repeated [ISO 19107]

**4.54****set**

unordered collection of related items (**objects** or values) with no repetition [ISO 19107]

**4.55****spatial object**

**object** used for representing a spatial characteristic of a feature [ISO 19107]

**4.56****tag <XML>**

the text in an XML document bounded by angle brackets

**EXAMPLE** <Road>.

**NOTE** A tag with no forward slash (e.g. <Road> ) is called a start tag (also opening tag), and one with a forward slash (e.g. </Road> is called an end tag (also closing tag).

**4.57****topological object**

**spatial object** representing spatial characteristics that are invariant under continuous transformations [ISO 19107]

**4.58****topology**

A branch of geometry describing the properties of a figure that are unaffected by continuous distortion [Collins Concise Dictionary]

**NOTE** Topology is mostly concerned with identifying the connectivity of networks and the adjacency of surfaces.

**4.59****tuple**

An ordered list of values

**4.60****type**

A class in a classification system

**NOTE** See also data type.

**4.61****Uniform Resource Identifier (URI)**

A unique identifier, usually taking the form of a short string or address that is used to identify the location of a resource

NOTE The general syntax is <scheme>::<scheme-specific-part>. The hierarchical syntax with a namespace is <scheme>://<authority><path>?<query> - see [RFC 2396].

## 5 Conventions

### 5.1 Deprecated parts of previous versions of GML

The verb "**deprecate**" provides notice that the referenced portion of the specification is being retained for backwards compatibility with earlier versions but may be removed from a future version of the specification without further notice.

### 5.2 Symbols (and abbreviated terms)

The following symbols and abbreviated terms are used in this document:

CRS	Coordinate Reference System
CSV	Comma Separated Values
CT	Coordinate Transformation
DTD	Document Type Definition
EPSG	European Petroleum Survey Group
GIS	Geographic Information System
GML	Geography Markup Language
HTTP	Hypertext Transfer Protocol
IETF	Internet Engineering Task Force
iff	if and only if
ISO	International Organization for Standardization
OGC	Open GIS Consortium
RDF	Resource Description Framework
RFC	Request for Comments
SMIL	Synchronized Multimedia Integration Language
SOAP	Simple Object Access Protocol
SVG	Scalable Vector Graphics
UML	Unified Modeling Language
URL	Uniform Resource Locator
WKT	Well-Known Text

WFS	Web Feature Service
XML	Extensible Markup Language
XSLT	eXtensible Stylesheet Language – Transformations
0D	Zero Dimensional
1D	One Dimensional
2D	Two Dimensional
3D	Three Dimensional

### 5.3 UML Notation

Many diagrams that appear in this standard are presented using the Unified Modeling Language (UML) static structure diagram. The UML notations used in this standard are described in the diagram below.

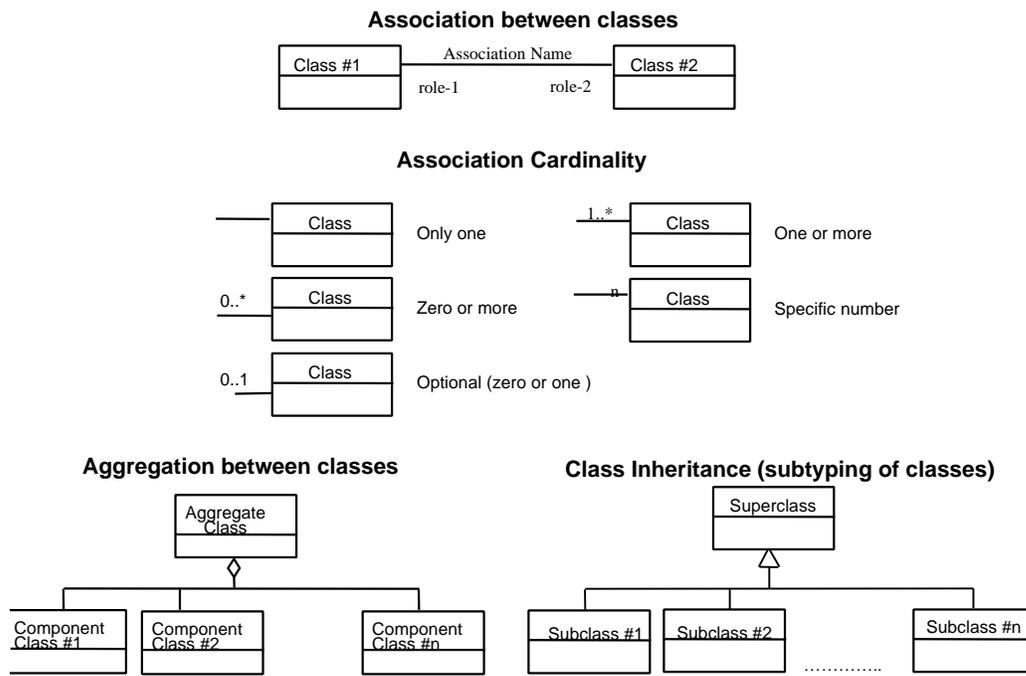

Figure 1 — UML notation

In this standard, the following stereotypes of UML classes are used:

- a) <<DataType>> A descriptor of a set of values that lack identity (independent existence and the possibility of side effects). A DataType is a class with no operations whose primary purpose is to hold the information.
- b) <<CodeList>> is a flexible enumeration that uses string values for expressing a list of potential values.
- c) <<Enumeration>> is a fixed list of valid identifiers of named literal values. Attributes of an enumerated type can only take values from this list.

- d) <<Union>> is a list of attributes. The semantics is that only one of the attributes can be present at any time.

In this standard, the following standard data types are used:

- a) `CharacterString` – A sequence of characters (in general this data type is mapped to “string” in XML Schema)
- b) `Integer` – An integer number (in general this data type is mapped to “integer” in XML Schema)
- c) `Real` – A floating point number (in general this data type is mapped to “double” in XML Schema)
- d) `Boolean` – A value specifying TRUE or FALSE (in general this data type is mapped to “boolean” in XML Schema)

## 5.4 XML Schema

The normative parts of the specification use the W3C XML Schema language to describe the grammar of conformant GML data instances. XML Schema is a rich language with many capabilities and subtleties. While a reader who is unfamiliar with XML Schema may be able to follow the description in a general fashion, this specification is not intended to serve as an introduction to XML Schema. In order to have a full understanding of this specification it is necessary for the reader to have a reasonable knowledge of XML Schema.

## 6 Overview of GML Schemas

### 6.1 Review of GML version 2 – XML for Simple Features

The previous major release of GML (version 2.x) was concerned with what the OGC calls simple features: features whose geometric properties are restricted to 'simple' geometries for which coordinates are defined in two dimensions and the delineation of a curve is subject to linear interpolation. These simple features in GML could be used to represent real-world phenomena. The task to which a digital representation will ultimately be put guides the classification of real world phenomena, which in turn determines the feature types that need to be defined.

For example, a city could be represented as a feature collection where the individual features represent such things as rivers, roads and colleges. Each of these feature types would have named, typed properties. The River feature type might have a property called name whose value shall be of the type 'string'. It is common practice to refer to the typed property; thus the River feature type is said to have a string property called name. Similarly, the Road feature type might have a string property called classification and an integer property called number. Properties with simple types (e.g. integer, string, float, boolean) are collectively referred to as simple properties.

The features required to represent a city might have geometry-valued properties as well as simple properties. Just like other properties, geometric properties shall be named. So the River feature type might have a geometric property called centerLineOf and the Road feature type might have a geometric property called linearGeometry. Just as it is common to have multiple simple properties defined on a single feature type, so too a feature type may have multiple geometric properties; the College feature type might have both a point property called location and a polygon property called campus.

### 6.2 GML version 3 – more than Simple Features, plus ISO conformance

This version of GML addresses the following needs that were not addressed or adequately met by version 2:

- represent geospatial phenomena in addition to simple 2D linear features, including features with complex, non-linear, 3D geometry, features with 2D topology, features with temporal properties, dynamic features, coverages, and observations;
- provide more explicit support for properties of features and other objects whose value is complex;
- represent spatial and temporal reference systems, units of measure and standards information;
- use reference system, units and standards information in the representation of geospatial phenomena, observations, and values;
- represent default styles for feature and coverage visualization;
- conform with standards from the ISO 19100 series.

The expansion of GML to meet these needs is reflected in base schemas for GML version 3 that are over eight times as large as the base schemas for GML version 2. However, few applications will use all of the definitions added to GML version 3. Implementers may use a selective subset of the GML version 3 schemas sufficient to support the definitions in their application schemas. Methods for modular use of GML are discussed in clause 20; a schema subsetting tool is provided in Annex G.

### 6.3 Backward compatibility

GML version 3.1.0 maintains backward compatibility for GML version 3.0.0 and 2.1.2 **instance documents** by preserving, but deprecating, some schema components that have been replaced by different constructs in the current version. GML version 2.1.2 and version 3.0.0 application schemas will in most cases require only minor changes to upgrade to GML version 3.1.0, removing the use of such deprecated schema components.

Deprecated GML schema components may be eliminated without notice from a future GML version.

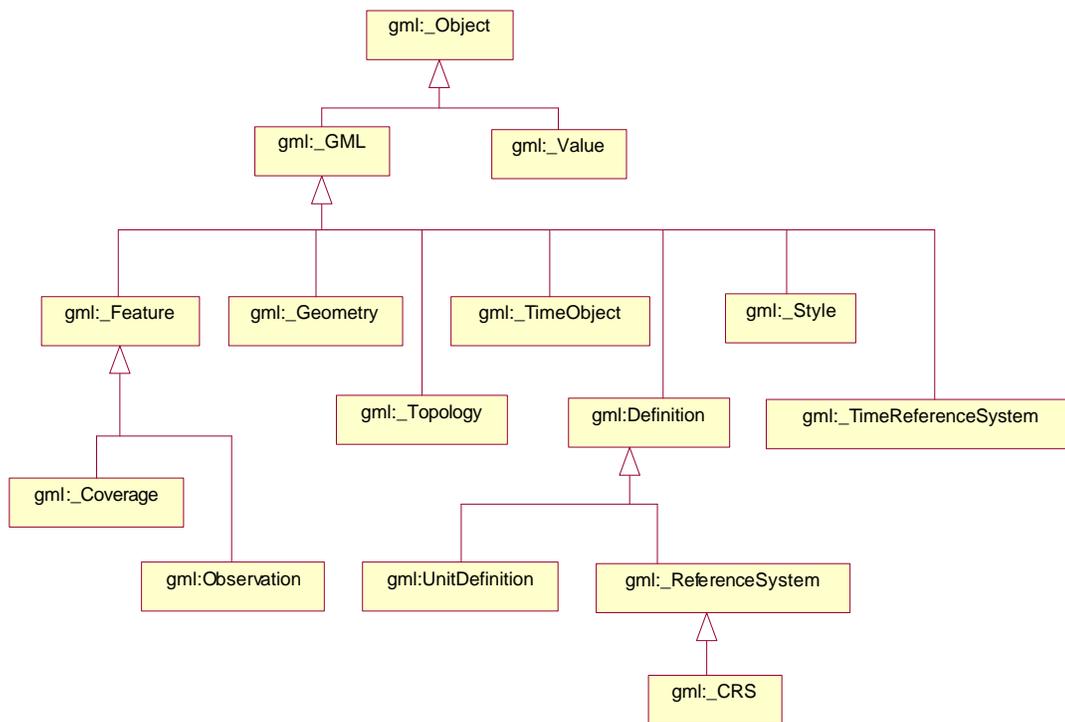

Deprecated GML schema components are written in *italics*.

### 6.4 GML 3 Application Schemas

Designers of GML Application schemas may extend or restrict the types defined in the GML base schemas to define appropriate types for an application domain. They may also use non-abstract elements and attributes from the GML base schemas as-is in an application schema if no changes are required. GML Application schemas may be constructed by hand using a text editor or specialized XML/Schema editor, in effect using XML/Schema as a conceptual schema language. GML Application schemas may also be constructed as part of a model driven process by automated translation to XML/Schema from conceptual models defined in other conceptual schema languages such as UML. In both cases, conformance with the requirements of this specification requires application schema use of all of the applicable GML base schema constructs, directly or by specialization, application schema validity according to the rules for XML/Schema, and application instance document data conformance to the application schema definitions verification by a validating XML parser. How the GML application schemas were produced is irrelevant for conformance to the requirements of this specification.

### 6.5 How GML 3 components are factored into schema documents

GML defines the various entities such as features, geometries, topologies etc. through a hierarchy of GML objects as shown in the UML diagram in Figure 2.

**Figure 2 — GML Class Hierarchy**

The items in Figure 2 with a preceding underscore (e.g. Feature) can be viewed as representative object instances of the class. The element `gml:_Feature`, for example, is to be interpreted as “any GML feature”.

The normative schemas of GML are organized in this specification around these GML object types.

Clause 7.2 describes the Xlink schema. This schema is an OGC implementation of the XLink specification using XML Schema. It may be replaced in some future release by an equivalent schema from the W3C.

Clause 7.3 defines the GML representation of some basic data types that are used in different GML Schemas. Most of these types are simple types or simple content types.

Clause 7.5 describes the schema `gmlBase.xsd`. This defines the root object (`gml:_Object`), the root of the GML class hierarchy (`gml:_GML`) and the root for MetaData property packages (`gml:_MetaData`).

Clause 8 describes the feature schema which defines `gml:_Feature` and some derived components.

Clauses 9, 10 and 11 describe the geometry schemas that define `gml:_Geometry` and some derived components.

Clause 12 describes the Coordinate Reference System schemas that define the sub-types of `gml:_ReferenceSystem`, and the elements and types required to construct specific Coordinate Reference Systems.

Clause 13 describes the schemas for Topology which define `gml:_Topology` and some derived components.

Clause 14 describes the schemas for temporal constructs and for dynamic features.

Clause 15 describes the schemas for definitions and dictionaries

Clause 16 describes the schemas for the construction of units of measure, measures and value objects.

Clause 17 describes the schemas for the description of Direction.

Clause 18 describes the schemas for Observations.

Clause 19.2 describes the schemas for grid geometries.

Clause 19.3 describes the schemas for coverages. This describes gml:\_Coverage and some derived components.

Clause 20 describes the schemas for the graphical default styling of GML features, geometries and topologies.

## 6.6 GML schemas to import into your GML 3 Application Schema

Most applications will make use of only a subset of the schemas described in this specification. Schema dependencies are discussed in greater detail in Clause 21. As a starting point, consider the following;

- a) If you are modelling geographic features you will need the feature.xsd.
- b) If your features have properties which make use of units of measure you will need to import one of the basicTypes.xsd, measure.xsd and valueObjects.xsd, but you will not need the units.xsd schema unless you are defining units of measure such as appear in a units of measure dictionary.
- c) If you need only simple 1D or 2D geometries you need only the geometryBasic0d1d and geometryBasic2d schemas. You need the additional geometry schemas only if you require support for complex, 3D or non-linear geometry types. This is discussed in greater detail in Clauses 9, 10 and 11.
- d) You only need topology.xsd if your features have topology properties.
- e) You need the Coordinate Reference System schemas only if you are constructing Coordinate Reference System dictionary entries and those for supporting components (e.g. Prime Meridians, Geodetic Datums etc.).
- f) You need the temporal schemas only if you are concerned with time dependent feature properties or dynamic features.
- g) You need the coverage schemas only if you are constructing coverages (e.g. remotely sensed images, aerial photographs, soil distribution, digital elevation models).
- h) You need the observation schema only if you are concerned with modelling acts of observation such as taking photographs or making measurements. In the latter case you will also likely use the valueObjects.xsd and measure.xsd schemas.
- i) You need direction schema only to describe direction constructs such as compass bearings. The direction schema is included by the observation.xsd schema in order to support directed observations.
- j) You need the defaultStyle.xsd only if you are concerned with the description of graphical styles for features, geometries and topologies.
- k) The Metadata element in gmlBase.xsd is used to define packages of metadata properties that can be attached to any resource including GML features, geometries, and topologies.

In many applications you will only need to import the feature.xsd as this transitively imports the simple geometry schemas and gmlBase.xsd. For a thorough discussion of schema dependencies and modularity see Clause 21.

## 7 GML schemas – general rules and base schemas

### 7.1 Introduction, namespaces, versioning

This clause describes the normative GML schema documents and explains their contents, structure and dependencies.

The components described in the `xlinks.xsd` schema document are in the `http://www.w3.org/1999/xlink` namespace, for which the prefix **xlink** is normally used.

All the other schema documents describe components in the `http://www.opengis.net/gml` namespace, for which the prefix **gml** is normally used.

Each schema document in GML carries a version attribute as defined in the XML Schema Recommendation. The format of the version attribute string is `x.y.z` where `x` denotes the major version number, `y` denotes a minor version number and `z` denotes a bug fix release for that document. The current version is 3.1.0.

### 7.2 Xlinks – Object Associations and Remote Properties

The normative xlink specification is available from W3C [xlink]. A schema document `xlinks.xsd` is provided as part of GML, pending the availability of a normative W3C XML Schema implementation.

Xlink components are used in GML to implement associations between objects by reference. GML property elements (see clause 7.5.3) may carry xlink attributes, which support the encoding of an association relationship by reference, the name of the property element denoting the target role in the association. The most important xlink component is:

**href:** Identifier of the resource which is the target of the association, given as a URI

The appearance of an `xlink:href` on a GML property indicates that the value of the property is to be found by traversing the link, that is the value is pointed to by the value of the `xlink:href` attribute. Following the terminology of Xlink, GML properties with `xlink:href` attributes are sometimes referred to as remote properties.

The other xlink components are used to indicate additional semantics of the relationship. The most useful of these are

**role:** description of the nature of the target resource, given as a URI

**arcrole:** description of the role or purpose of the target resource in relation to the present resource, given as a URI

**title:** description of the association or the target resource, given as text.

For complete definitions of these and other xlink components, including their use in extended xlink association maps, refer to the xlink specification [xlink].

In the GML core schemas (those defined in Clauses 7 to 20 of this international standard), simple xlinks are used exclusively to denote object, feature or geometry associations and to denote remotely referenced property values.

### 7.3 Basic Types

#### 7.3.1 Overview

W3C XML Schema provides a set of built-in “simple” types which define methods for representing values as literals without internal markup. These are described in Part 2 of the W3C XML Schema recommendation. Because GML is an XML encoding in which instances are described using XML Schema, these simple types

are used as far as possible and practical for the representation of data types. W3C XML Schema also provides methods for defining (i) new simple types by restriction and combination of the built-in types, and (ii) complex types, with simple content, but which also have XML attributes. In many places where a suitable built-in simple type is not available, simple content types derived using the XML Schema mechanisms are used for the representation of data types in GML.

A set of these simple content types that are required by several GML components are defined in the basicTypes schema document, as well as some elements based on them,. These are primarily based around components needed to record amounts, counts, flags and terms, together with support for exceptions or null values. The basic types and elements described in the basicTypes schema listed in Annex C. The schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:basicTypes:v3.1.0
```

## 7.3.2 Convenience types

### 7.3.2.1 gml:NullType

gml:NullType defines a content model that allows recording of a typed exception.

```
<simpleType name="NullEnumeration">
  <restriction base="string">
    <enumeration value="inapplicable"/>
    <enumeration value="missing"/>
    <enumeration value="template"/>
    <enumeration value="unknown"/>
    <enumeration value="withheld"/>
  </restriction>
</simpleType>

<simpleType name="NullType">
  <union memberTypes="gml:NullEnumeration anyURI"/>
</simpleType>
```

NullType is a union of the following enumerated values:

- inapplicable** there is no value
  - missing** the correct value is not readily available to the sender of this data. Furthermore, a correct value may not exist
  - template** the value will be available later
  - unknown** the correct value is not known to, and not computable by, the sender of this data. However, a correct value probably exists
  - withheld** the value is not divulged
- and
- anyURI** which should refer to a resource which describes the reason for the value not being available

A particular community may choose to assign more detailed semantics to the standard values provided. Alternatively, the URI method enables a specific or more complete explanation for the absence of a value to be provided elsewhere and indicated by-reference in an instance document.

NullType is used as a member of a union in a number of simpleContent types defined below (clauses 7.3.2.3, 7.3.3.3, 7.3.4.3) where it is necessary to permit a value from the NullType union as an alternative to the primary type.

### 7.3.2.2 gml:Null

A convenience element gml:Null is declared as follows:

```
<element name="Null" type="gml:NullType"/>
```

This element might appear in data instance documents as follows:

```
<gml:Null>withheld</gml:Null>  
<gml:Null>http://my.big.org/explanations/theDogAtelt</gml:Null>
```

The first example uses one of the built-in values for Null. The second example contains a reference to an explanation available elsewhere, identified by a URI.

The purpose in providing the gml:Null element is as follows. In order to construct a content model where a value may be omitted, the cardinality constraint expressed in XML Schema using the construction ‘minOccurs=’0’ might be used. However, this approach carries the risk that the reason for the value not being present may be misinterpreted. As an alternative the element gml:Null may be included as a member of a <choice> group, alongside an element of the datatype of a “normal” value. For example, the content model described by the schema fragment

```
<element name="footprint">  
  <complexType>  
    <choice>  
      <element ref="gml:Envelope"/>  
      <element ref="gml:Null"/>  
    </choice>  
  </complexType>  
</element>
```

allows either of the following data instances to be valid:

```
<footprint>  
  <gml:Envelope> ... </gml:Envelope>  
</footprint>  
  
<footprint>  
  <gml:Null>inapplicable</gml:Null>  
</footprint>
```

This allows the hypothetical element “footprint” to appear in an instance document, optionally containing an explicit marker indicate why it has no value, instead of having semantics inferred from the absence of a value.

The <choice> group is a useful content model structure available in the W3C XML Schema language, which shall be synthesised using more complex notation in some other conceptual schema languages (e.g. using a <<union>> stereotype, or an OCL constraint, in UML). It is an efficient and useful structuring component provided by this implementation language, so is used widely in GML as illustrated here and elsewhere.

### 7.3.2.3 gml:SignType

This is a convenience type with values “+” (plus) and “-” (minus).

```
<simpleType name="SignType">  
  <restriction base="string">  
    <enumeration value="-"/>  
    <enumeration value="+"/>  
  </restriction>  
</simpleType>
```

Elements or attributes of this type are used in various places, e.g. to indicate the direction of topological objects with "+" for forwards, or "-" for backwards.

### 7.3.3 Simple content

#### 7.3.3.1 gml:booleanOrNull, gml:doubleOrNull, gml:integerOrNull, gml:NameOrNull, gml:stringOrNull

A set of simple types provide extensions to the XML Schema built-in types boolean, double, integer, Name and string, to allow a choice of either the built-in simple type or a null. They are constructed as follows:

```
<simpleType name="booleanOrNull">
  <union memberTypes="gml:NullEnumeration boolean anyURI"/>
</simpleType>
```

```
<simpleType name="doubleOrNull">
  <union memberTypes="gml:NullEnumeration double anyURI"/>
</simpleType>
```

```
<simpleType name="integerOrNull">
  <union memberTypes="gml:NullEnumeration integer anyURI"/>
</simpleType>
```

```
<simpleType name="NameOrNull">
  <union memberTypes="gml:NullEnumeration Name anyURI"/>
</simpleType>
```

```
<simpleType name="stringOrNull">
  <union memberTypes="gml:NullEnumeration string anyURI"/>
</simpleType>
```

These are defined as unions of the respective XML Schema built-in simple type and the GML Nulltype. An element which uses one of these types may have content which is either boolean/string/Name/double/integer or a value from the Nulltype.

#### 7.3.3.2 gml:CodeType

This is a generalized type to be used for a term, keyword or name.

```
<complexType name="CodeType">
  <simpleContent>
    <extension base="string">
      <attribute name="codeSpace" type="anyURI" use="optional"/>
    </extension>
  </simpleContent>
</complexType>
```

It adds a XML attribute codeSpace to a term, where the value of the codeSpace attribute (if present) should indicate a dictionary, thesaurus, classification scheme, authority, or pattern for the term. As an example, the gmlBase schema contains an element declaration using this type (clause 7.5.6.3):

```
<element name="name" type="gml:CodeType"/>
```

so a corresponding element might appear in an instance document as follows :

```
<gml:name codeSpace = "http://www.ukusa.gov/placenames">St Paul</gml:name>
```

In this example "St Paul" is asserted to be a meaningful name according to <http://www.ukusa.gov/placenames>. Note that in all cases the rules for the values, including such things as uniqueness constraints, are set by the authority responsible for the codeSpace.

### 7.3.3.3 gml:MeasureType

A MeasureType supports recording Type is an amount encoded as a double, together with a units of measure indicated by a uom attribute. The value of uom (Units Of Measure) attribute is a reference to a reference system for the amount, often a ratio or interval scale.

```
<complexType name="MeasureType">
  <simpleContent>
    <extension base="double">
      <attribute name="uom" type="anyURI" use="required"/>
    </extension>
  </simpleContent>
</complexType>
```

The value of uom (Units Of Measure) attribute is a reference to a reference system for the amount, often a ratio or interval scale.

As an example, an application schema may contain an element declaration using this type

```
<element name="height" type="gml:MeasureType"/>
```

Also corresponding n elements of this type might appear in an data instance document as follows :

```
<height uom="http://www.iso.org/iso/en/.../units/m">1.4224</height>
<height uom="http://www.equestrian.org/units/hands">14</height>
<height uom="http://www.iso.org/iso/en/.../units/m">1.4224</height>
```

where the resource identified by the value of the uom attribute defines the unit of measure. GML components for this are defined in clause 16.2.

### 7.3.4 Lists

#### 7.3.4.1 gml:booleanList, gml:doubleList, gml:integerList, gml:NameList, gml:NCNameList, gml:QNameList, gml:booleanOrNullList, gml:NameOrNullList, gml:doubleOrNullList, gml:integerOrNullList

A set of types for lists of simple values are constructed according to the following patterns as follows:

```
<simpleType name="booleanList">
  <list itemType="boolean"/>
</simpleType>

<simpleType name="doubleList">
  <list itemType="double"/>
</simpleType>

<simpleType name="integerList">
  <list itemType="integer"/>
</simpleType>

<simpleType name="NameList">
  <list itemType="Name"/>
</simpleType>

<simpleType name="NCNameList">
  <list itemType="NCName"/>
</simpleType>

<simpleType name="QNameList">
  <list itemType="QName"/>
</simpleType>
```

```

<simpleType name="booleanOrNullList">
  <list itemType="gml:booleanOrNull"/>
</simpleType>

<simpleType name="NameOrNullList">
  <list itemType="gml:NameOrNull"/>
</simpleType>

<simpleType name="doubleOrNullList">
  <list itemType="gml:doubleOrNull"/>
</simpleType>

<simpleType name="integerOrNullList">
  <list itemType="gml:integerOrNull"/>
</simpleType>

```

These types are defined as a list of values of the respective XML Schema built-in simple types, or of the Union types listed above. The \*OrNullList types support null values interspersed within a list.

An element which uses one of these types will contain a whitespace-separated list of members of the relevant type (see <http://www.w3.org/TR/xmlschema-2/#atomic-vs-list> for more details of the XML list structure).

**NOTE** None of list types defined here use an XML Schema string as an item. The reason for this is that a string may include embedded spaces, linefeeds, etc (<http://www.w3.org/TR/xmlschema-2/#string>). Since whitespace acts as the item separator in a list instance, there would be ambiguity in identifying items that potentially contain whitespace. On the other hand, an instance of the XML Schema Name type may not contain whitespace (<http://www.w3.org/TR/2000/WD-xml-2e-20000814#NT-Name>), so this may be used safely in a list context. The corollary of this is that if a term may contain whitespace, then such a term may not occur in a list instance.

#### 7.3.4.2 gml:CodeListType, gml:CodeOrNullListType

These two types provide for lists of terms. The schema definitions are as follows:

```

<complexType name="CodeListType">
  <simpleContent>
    <extension base="gml:NameList">
      <attribute name="codeSpace" type="anyURI" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<complexType name="CodeOrNullListType">
  <simpleContent>
    <extension base="gml:NameOrNullList">
      <attribute name="codeSpace" type="anyURI" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

```

The values in an instance element of CodeListType should all be valid according to the rules of the dictionary, classification scheme, or authority identified by the value of its codeSpace attribute (e.g. list of localities, soil types, rock types, animal species etc.). As an example, an application schema may contain an element declaration using this type

```
<element name="species" type="gml:CodeListType"/>
```

so a corresponding element might appear in an instance document as follows :

```
<species codeSpace="http://my.big.org/florelegium">dryandra banksia hardenbergia lavendar</species>
```

where the listed items are from "http://my.big.org/florelegium" which is a (hypothetical) list of flowers.

An instance element of CodeOrNullListType may also include embedded values from NullType. It is intended to be used in situations where a term or classification is expected, but the value may be absent for some reason.

### 7.3.4.3 gml:MeasureListType, gml:MeasureOrNullListType

These two types provide for lists of quantities. The schema definitions are as follows:

```
<complexType name="MeasureListType">
  <simpleContent>
    <extension base="gml:doubleList">
      <attribute name="uom" type="anyURI" use="required"/>
    </extension>
  </simpleContent>
</complexType>

<complexType name="MeasureOrNullListType">
  <simpleContent>
    <extension base="gml:doubleOrNullList">
      <attribute name="uom" type="anyURI" use="required"/>
    </extension>
  </simpleContent>
</complexType>
```

As an example, an application schema may contain element declarations using these types

```
<element name="heights" type="gml:MeasureListType"/>
<element name="weights" type="gml:MeasureOrNullListType"/>
```

so corresponding elements might appear in an instance document as follows:

```
<heights uom="http://www.iso.org/iso/en/.../units/m">1.76 1.85 1.56 1.98</heights>
<weights uom="http://www.iso.org/iso/en/.../units/kg">67.0 73.4 withheld 85.1</weights>
```

In both examples all of the values in the list are described using the same scale. In the second example a null value appears where a measure is normally expected, but the value may be absent for some reason.

## 7.4 GML model and syntax

### 7.4.1 GML instance documents

GML uses an explicit syntax to instantiate a GML application schema conformant with the General Feature Model defined in ISO 19109 in an XML document.

A Feature (ISO 19109) is encoded as an XML element with the name of the feature type. Other identifiable objects are encoded as XML elements with the name of the object type.

Each feature attribute (ISO 19109) and feature association role (ISO 19109) is a property of a feature. Feature properties are encoded in an XML element.

**NOTE** The term "attribute" in XML refers to a specific syntactic component in XML documents, so to avoid confusion when describing the XML encoding, GML follows RDF (W3C, 1999) terminology and uses the term property rather than attribute or association role. The General Feature Model (ISO 19109) also uses the term "property" as a generalization of attributes, association roles and operations.

Furthermore, the property semantics, which is indicated by the name of the element representing the property, and the property value, which is given by the content of the property element, are distinguished. A property element may contain its value as content encoded inline, or reference its value with a simple XLink. The value of a property may be simple, or it may be a feature or other complex object. When recorded inline, the value

of a simple property is recorded as a literal value with no embedded markup (text), while if the value is complex it appears as a subtree using XML markup (i.e. an XML element with possible sub-structure).

**NOTE** The GML model has a relatively straightforward representation using the UML profile used in the ISO 19100 series (defined in ISO 19103). This is described in detail in Annex D and Annex E, but can be summarised approximately and briefly as follows.

Features are represented

- in UML by objects, where the name of the feature type is used as the name of the object class
- in GML instances by XML elements, where the name of the feature type is used as the name of the element

Feature properties are represented

- in UML by association roles with feature type classes, and attributes of feature type classes, where the property semantics are given by the association role name or attribute name
- in GML instances by sub-elements (known as property elements) of feature elements, where the property semantics are given by the property element name

The property value has a type indicated

- in UML by the class of the association target, or by the datatype of the attribute
- in GML, in the case of properties with complex values, by the name of the object element contained within the property element

The result is a layered XML document, in which XML elements corresponding to features, objects or values occur interleaved with XML elements corresponding to the properties that relate them. The function of a feature, object or value in context can always be determined by inspecting the name of the property element which directly contains it, or which carries the reference to it.

#### 7.4.2 Lexical conventions

There are several lexical conventions used in GML to assist in human comprehension of GML instances and schemas:

- objects are instantiated as XML elements with a conceptually meaningful name in UpperCamelCase;
- properties are instantiated as XML elements whose name is in lowerCamelCase;
- abstract elements have an underscore prepended to their `_name`;
- the names of XML Schema complex types are in UpperCamelCase ending in the word "Type";
- abstract XML Schema types have the word "Abstract" prepended.

#### 7.4.3 XML schema definition of GML languages

GML schema documents are W3C XML Schemas that define types and declare

- XML elements to encode GML objects with identity,
- XML elements to encode GML properties of those objects, and
- XML attributes qualifying those properties.

A GML object is an XML element of a type derived directly or indirectly from `AbstractGMLType`. From this derivation, a GML object may have a `gml:id` attribute.

A GML property may not be derived from `AbstractGMLType`, may not have a `gml:id` attribute, or any other attribute of XML type ID.

An element is a GML property if and only if it is a child element of a GML object.

No GML object may appear as the immediate child of a GML object.

Consequently, no element may be both a GML object and a GML property.

NOTE In this version of GML, the use of additional XML attributes in a GML application schema is discouraged.

## 7.5 `gmlBase` schema

The types and elements used to establish the GML model and syntax are described in the schema listed in Annex C. The schema is identified by the following location-independent name (using URN syntax):

`urn:opengis:specification:gml:schema-xsd:gmlBase:v3.1.0`

### 7.5.1 Goals of base schema

The schema document `gmlBase.xsd` defines components that establish the GML Model and Syntax: in particular

- a root XML type from which XML types for all GML objects should be derived,
- a pattern and components for GML properties,
- patterns for collections and arrays, and components for generic collections and arrays,
- components for associating metadata with GML objects,
- components for constructing definitions and dictionaries.

### 7.5.2 Base objects

#### 7.5.2.1 `gml:_Object`

An abstract convenience element `gml:_Object` is declared as follows:

```
<element name="_Object" abstract="true">
```

This element has no type defined, and is therefore implicitly an XML Schema “anyType”. It is used as the head of an XML Schema substitution group which unifies `complexContent` and certain `simpleContent` elements used for datatypes in GML, including the `gml:_GML` substitution group.

NOTE `gml:_Object` is defined primarily to act as a variable in certain aggregate patterns where it is necessary to allow either elements in the `gml:_GML` substitution group, or certain `complexContent` or `simpleContent` elements to be valid in an instance.

A GML dataset (also called a data instance or data document) is a GML object. This GML object can in turn be a collection of GML objects

#### 7.5.2.2 `gml:_GML`, `gml:AbstractGMLType`

The most basic components for constructing identifiable GML objects are described in the schema as follows:

```

<element name="_GML" type="gml:AbstractGMLType" abstract="true" substitutionGroup="gml:_Object"/>
<complexType name="AbstractGMLType" abstract="true">
  <sequence>
    <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="gml:description" minOccurs="0"/>
    <element ref="gml:name" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <attribute ref="gml:id" use="optional"/>
</complexType>

```

The abstract element `gml:_GML` is “any GML object having identity”. It acts as the head of an XML Schema substitution group, which may include any element which is a GML feature, or other object, with identity. This is used as a variable in content models in GML core and application schemas. It is effectively an abstract superclass for all GML objects.

The pairing of `gml:_GML` and `gml:AbstractGMLType` shows a basic pattern used in the GML schemas, whereby each GML object type is represented by a global element declaration, which has an associated XML Schema type definition. The name of an element representing a GML Object indicates the conceptual meaning of the object. Generic element names in GML include `gml:_Object`, `gml:_GML`, `gml:_Feature`, `gml:_Value`, `gml:_Coverage`, `gml:_Topology` and `gml:_CRS`. These other generic elements representing objects are defined elsewhere in this specification.

The child XML elements and XML attributes of a GML object are properties of that object. Thus an object represented by an `gml:_GML` element has four properties: `metaDataProperty`, `description`, `name` and `id`. These are described in clause 7.5.5.

### 7.5.3 GML properties

The term “property” is used to refer to a GML property, which is any characteristic of a GML object. An element in a GML document or data stream is a GML property if and only if it is a child element of a GML object element. The meaning of each property is indicated by the name of the element that instantiates it.

GML Objects may have an unlimited number of properties, in addition to those inherited from `gml:AbstractGMLType`. A property may be defined to have either simple or complex content. A property with simple content has an XML Schema `simpleContent` type, as illustrated by the case of the standard property elements `gml:description` and `gml:name`. A property with complex content has an XML Schema `complexContent` type, as in the case of the standard property element `gml:member`.

Property elements may use two modes:

- by value: the value of the property is represented directly, as the content of the property element. This method is used by the standard property `gml:name` and may be used for `gml:description` (see clause 7.5.6).
- by reference: the value of the property is available elsewhere, and is identified by the value of an **xlink:href** attribute on the property element. This alternative method may be used for the standard property `gml:description` (see clause 7.5.6).

#### 7.5.3.1 `gml:_association`, `gml:AssociationType`

To support the encoding of properties that may have complex content, a basic pattern for property elements is provided in the schema as follows:

```

<element name="_association" type="gml:AssociationType" abstract="true"/>
<complexType name="AssociationType">
  <sequence>
    <element ref="gml:_Object" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>

```

```
</complexType>
```

NOTE The declaration of `gml:_association` and its accompanying type definition is provided for convenience, to act as a template or pattern for the construction of property elements in application schemas. There is no requirement for specific properties to use XML Schema type derivation from `gml:AssociationType` to create properties in a conformant GML application schema. This contrasts with the requirement that the content model for all identifiable objects shall derive from `gml:AbstractGMLType`, and for all features from `gml:AbstractFeatureType`

### 7.5.3.2 `gml:AssociationAttributeGroup`

XLink components are the standard method to support hypertext referencing in XML. An XML Schema attribute group, `gml:AssociationAttributeGroup`, is provided to support the use of Xlinks as the method for indicating the value of a property by reference in a uniform manner in GML. This attribute group is defined in the schema as follows:

In `xlinks.xsd` (see clause 7.2):

```
<attributeGroup name="simpleLink">
  <attribute name="type" type="string" fixed="simple" form="qualified"/>
  <attribute ref="xlink:href" use="optional"/>
  <attribute ref="xlink:role" use="optional"/>
  <attribute ref="xlink:arcrole" use="optional"/>
  <attribute ref="xlink:title" use="optional"/>
  <attribute ref="xlink:show" use="optional"/>
  <attribute ref="xlink:actuate" use="optional"/>
</attributeGroup>
```

in `gmlBase.xsd` (see clause 7.5):

```
<attributeGroup name="AssociationAttributeGroup">
  <attributeGroup ref="xlink:simpleLink"/>
  <attribute ref="gml:remoteSchema" use="optional"/>
</attributeGroup>
```

The value of a GML property that carries an `xlink:href` attribute is the resource returned by traversing the link.

In addition to the `simpleLink` components, the additional attribute **remoteSchema**, is provided to indicate a schema which constrains the description of the remote resource referenced by the `xlink`. Note that all components in the attribute group are optional.

### 7.5.4 By value or by reference?

The `gml:_Object` element in the content model for properties is optional. In combination with the component cardinalities in `AssociationAttributeGroup` this means that an element of this type may have a content element (in the substitution group headed by `gml:_Object`) or `xlink` attributes. GML property elements which follow this pattern can be used to attach values either by value or by reference.

NOTE When used in the “by value” form, a GML property element corresponds with an implementation of a UML composition association. When used in the “by reference” form, a GML property element corresponds with an implementation of a UML aggregation association. The standard form, which supports either style, may be compared with the UML untyped association. The name of the property element corresponds to the rolename on the UML association, or to a UML attribute name. The name of the value element (`gml:Point` in the example here) corresponds to the class of the target of the association.

EXAMPLE A utility property provided for GML Features (described below in Clause 8.2.3) is “position”. This may be used to indicate a spatial location by-value as follows:

```
<gml:position>
  <gml:Point gml:id="point96" srsName="urn:EPSG:geographicCRS:62836405">
    <gml:pos>-31.936 115.834</gml:pos>
  </gml:Point>
</gml:position>
```

```
</gml:Point>
</gml:position>
```

which uses the gml:Point object as defined in the GML geometry schemas (described in Clause 9.2). The same property element may be used to indicate a location by reference as follows:

```
<gml:position xlink:href="http://my.big.org/locations/point53"/>
```

where "http://my.big.org/location/point53" identifies a point supplied by the service indicated.

However, a property element following this pattern may have no content or attributes, or it may have both content and attributes, and still be XML Schema-valid. It is not possible to constrain the co-occurrence of content or attributes, so we cannot use W3C XML Schema to restrict a property to be exclusively by-value or by-reference.

#### 7.5.4.1 gml:\_strictAssociation

The constraint may be described precisely using an auxiliary constraint language Schematron [schematron]. The abstract, global elements **\_association** and **\_strictAssociation** both use **AssociationType**, but the following schema fragments shows how an element declaration may include a Schematron constraint to limit the property to act in either by-value or by-reference mode, but not both.

```
<appinfo>
  <sch:title>Schematron validation</sch:title>
  <sch:ns prefix="gml" uri="http://www.opengis.net/gml"/>
  <sch:ns prefix="xlink" uri="http://www.w3.org/1999/xlink"/>
  <sch:pattern name="Check either href or content not both">
    <sch:rule abstract="true" id="hrefOrContent">
      <sch:report test="@xlink:href and (*|text())">
        Property element may not carry both a reference to an object and contain an object.</sch:report>
      <sch:assert test="@xlink:href | (*|text())">
        Property element shall either carry a reference to an object or contain an object.</sch:assert>
    </sch:rule>
  </sch:pattern>
</appinfo>

<element name="_strictAssociation" type="gml:AssociationType" abstract="true">
  <annotation>
    <appinfo>
      <sch:pattern name="refAndContent co-occurrence prohibited">
        <sch:rule context="gml:_strictAssociation">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
    <documentation>shall carry a reference to an object or contain an object but not both</documentation>
  </annotation>
</element>
```

NOTE Some XML validators will process the Schematron constraints automatically. Otherwise, the Schematron code can be treated merely as a formal description of the required constraint. It is included here primarily as an illustration of how this might be used for specific purposes by application schema developers.

#### 7.5.4.2 gml:\_reference, gml:ReferenceType

Finally, in order to support the encoding of properties whose value is provided remotely by-reference (i.e. implementing the UML aggregation association), the following components are provided:

```
<element name="_reference" type="gml:ReferenceType" abstract="true"/>

<complexType name="ReferenceType">
  <sequence/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
```

```
</complexType>
```

The element `gml:_reference` is abstract, and thus may be used as the head of a substitution group of more specific elements providing a value by reference.

## 7.5.5 Convenience properties and property types

### 7.5.5.1 `gml:member`

A concrete property element named “member” with complex content is declared in `gmlBase`:

```
<element name="member" type="gml:AssociationType"/>
```

This is primarily to support the construction of object collections. In an instance document this element may be used in a data instance as follows:

```
<gml:member xlink:href="http://my.org/thingie#i456" gml:remoteSchema="http://my.org/schemas/thingie.xsd"/>
```

where the value is given by reference, or

```
<gml:member>
  <my:Thingie gml:id="i456" ... />
</gml:member>
```

where the value is encoded inline. Since `gml:_Object` is an abstract element, in this real instance it is replaced by a concrete element in its substitution group. The following element definition in the “`http://my.org/schemas/thingie.xsd`” application schema where `my:ThingyType` is defined supports this replacement:

```
<element name="Thingie" type="my:ThingyType" substitutionGroup="gml:_Object"/>
```

### 7.5.5.2 `gml:stringOrRefType`

`gml:StringOrRefType` is provided to contain extended text values. It is defined in the schema document as follows:

```
<complexType name="StringOrRefType">
  <simpleContent>
    <extension base="string">
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </extension>
  </simpleContent>
</complexType>
```

It is an implementation of the GML property model in a `simpleContent` type.

NOTE This is possible because an empty string is schema-valid.

This type is available wherever there is a need for a “text” type property. It is of string type, so the text can be included inline, but the value can also be referenced remotely via `xlinks` which are in the `AssociationAttributeGroup`. If the remote reference is present, then the value obtained by traversing the link should be used if possible, and the string content of the element can be used for an annotation.

## 7.5.6 Standard properties of GML Objects

XML Schema types for all concrete GML objects derive from `gml:AbstractGMLType`. This means that all GML objects inherit certain standard properties that are included in the content model of `gml:AbstractGMLType`.

### 7.5.6.1 gml:metaDataProperty

```
<element name="metaDataProperty" type="gml:MetaDataPropertyType"/>
```

This property contains or refers to a metadata package that contains metadata properties. More detail is provided below in clause 7.5.8.

### 7.5.6.2 gml:description

```
<element name="description" type="gml:StringOrRefType"/>
```

The value of this property is a text description of the object. **description** uses the GML **StringOrRefType** defined in clause 7.5.5.2, so may contain a simple text string content, or carry a reference to an external description.

### 7.5.6.3 gml:name

```
<element name="name" type="gml:CodeType"/>
```

This property provides a label for the object, commonly a descriptive name.

An object may have several names, typically assigned by different authorities. **gml:name** uses the GML **CodeType** content model. The authority for a name is indicated by the value of its (optional) **codeSpace** attribute. The name may or may not be unique, as determined by the rules of the organization responsible for the codeSpace. In common usage there will be one name per authority, so a processing application may select the name from its preferred codeSpace.

### 7.5.6.4 gml:StandardObjectProperties

The three preceding property elements are collected in a model group **gml:StandardObjectProperties**, defined as follows:

```
<group name="StandardObjectProperties">
  <sequence>
    <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="gml:description" minOccurs="0"/>
    <element ref="gml:name" minOccurs="0" maxOccurs="unbounded">
      <annotation>
        <documentation>Multiple names may be provided. These will often be distinguished by being assigned by different
        authorities, as indicated by the value of the codeSpace attribute. In an instance document there will usually only be one
        name per authority. </documentation>
      </annotation>
    </element>
  </sequence>
</group>
```

This is provided for convenience in the construction of application schema, particularly when it is desired to define types derived by restriction from **gml:AbstractGMLType** and **gml:AbstractFeatureType**. Derivation by restriction requires that all components that are used unchanged are copied down into the new type definition. As an alternative to including three lines for **gml:metaDataProperty**, **gml:description** and **gml:name**, a one line reference to **gml:StandardObjectProperties** may be used instead:

```
<group ref="gml:StandardObjectProperties"/>
```

### 7.5.6.5 gml:id

```
<attribute name="id" type="ID"/>
```

This property supports provision of a database handle for the object. Its use is optional but recommended. It is of XML type **ID**, so is constrained to be unique in the XML document within which it occurs. An external

identifier for the object in the form of a URI may be constructed using standard methods [URI]. This is done by concatenating the URI for the document, a fragment separator "#", and the value of the attribute of XML type ID.

## 7.5.7 Bags and arrays

### 7.5.7.1 gml:ArrayAssociationType

For a property that can have multiple values all with the same relationship to the containing object, the cardinality of the association is extended as follows:

```
<complexType name="ArrayAssociationType">
  <sequence>
    <element ref="gml:_Object" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</complexType>

<element name="members" type="gml:ArrayAssociationType"/>
```

This property element may appear in a data instance as follows:

```
<gml:members>
  <my:Thingie gml:id="i456" />
  <my:Thingie gml:id="i457" />
  <my:Thingie gml:id="i458" />
</gml:members>
```

### 7.5.7.2 gml:Array, gml:ArrayType, gml:Bag, gml:BagType

Two concrete object elements are provided for generic arrays and bags. The schema constructions are as follows:

```
<complexType name="ArrayType">
  <complexContent>
    <extension base="gml:AbstractGMLType">
      <sequence>
        <element ref="gml:members" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Array" type="gml:ArrayType" substitutionGroup="gml:_GML"/>
```

intended to be used for a collection whose member objects are of homogeneous type and where their order is significant, and

```
<complexType name="BagType">
  <complexContent>
    <extension base="gml:AbstractGMLType">
      <sequence>
        <element ref="gml:member" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:members" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Bag" type="gml:BagType" substitutionGroup="gml:_GML"/>
```

for general collections with no implication about the type, order or uniqueness of the member objects.

## 7.5.8 Metadata

### 7.5.8.1 gml:metaDataProperty, gml:metaDataPropertyType, gml:\_MetaData, gml:AbstractMetaDataType

The metaDataProperty follows the property pattern and is used to contain or refer to metadata for GML objects. It is defined in the schema as follows:

```
<complexType name="MetaDataType">
  <choice minOccurs="0">
    <element ref="gml:_MetaData" minOccurs="0"/>
    <any processContents="lax"/>
  </choice>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
  <attribute name="about" type="anyURI" use="optional"/>
</complexType>

<element name="metaDataProperty" type="gml:MetaDataType"/>
```

The optional “about” attribute carries a URI which points to an element or range of elements, or other resource to which this metadata refers.

The value of the metaDataProperty is an abstract element gml:\_MetaData that acts as a placeholder for “any package of metadata properties”, defined as follows:

```
<complexType name="AbstractMetaDataType" abstract="true" mixed="true">
  <attribute ref="gml:id" use="optional"/>
</complexType>

<element name="_MetaData" type="gml:AbstractMetaDataType" abstract="true" substitutionGroup="gml:_Object"/>
```

It is used as follows:

1. The user defines or re-uses an existing metadata schema. The structure of this metadata schema is more or less arbitrary but should satisfy the following pattern:
  - The metadata schema shall declare a single root element. This element shall be substitutable for gml:\_MetaData – i.e. it is derived from AbstractMetaDataType
  - The content model of this root element shall be an XML Schema ComplexType that derives by extension from gml:AbstractMetaDataType.
  - The content model of this root element shall consist of an XML model group of elements each of which is a metadata property (e.g. age, accuracy, creation date etc.) of the object to which the gml:metaDataProperty is attached.
  - If the user wishes to more strongly restrict the value of the gml:metaDataProperty, the application schema designer shall define a new property that is an XML Schema restriction of gml:metaDataProperty.
2. The metaDataProperty in the data instance points to or includes the values of the metadata properties defined by the schema in 1. above.
3. The metaDataProperty is used in one of two ways:
  - The metadata schema shall declare a single root element. This element shall be substitutable for gml:\_MetaData.
  - Attached to a GML object and without the “gml:about” attribute it provides metadata for the GML object to which it is attached.

- Attached to a GML object collection and with the gml:about attribute it provides metadata for the GML objects within the object collection referenced by the gml:about attribute, the value of which is an XPointer expression.

Alternatively, any other existing metadata syntax in XML can be used instead of an element substitutable for gml:\_MetaData due to the

```
<any processContents="lax"/>
```

declaration.

If metadata following the conceptual model of ISO 19115:2003 shall be encoded in a GML document, the corresponding Implementation Specification specified in ISO WD 19139 shall be used to encode the metadata information.

### 7.5.8.2 gml:GenericMetaData, gml:GenericMetaDataType

For convenience, a generic concrete MetaData element has been provided in GML 3.0.0. This element is deprecated with GML 3.1.0.

```
<complexType name="GenericMetaDataType" mixed="true">
  <complexContent mixed="true">
    <extension base="gml:AbstractMetaDataType">
      <sequence>
        <any processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="GenericMetaData" type="gml:GenericMetaDataType" substitutionGroup="gml:_MetaData"/>
```

This element has been intended to act as a container for metadata encoded using XML but defined in external schemas, in cases where it is not possible to assign the concrete components to the GML \_MetaData substitution group. With GML 3.1.0 such metadata elements can be direct children of a gml:metadataProperty element.

## 8 GML schemas – feature model

### 8.1 General Concepts

A GML feature is a meaningful object in the selected domain of discourse such as a Road, River, Person, Vehicle or Administrative Area. This follows the general definition of a feature given in ISO 19109 and the OGC Abstract Specification Topic 5.

### 8.2 Feature schema

The feature schema, feature.xsd, provides a framework for the creation of GML features and feature collections. These are described in the schema listed in Annex C. The feature schema includes a basic geometry schema (geometryBasic2d.xsd).

The feature schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:feature:v3.1.0
```

## 8.2.1 Features

### 8.2.1.1 gml:AbstractFeatureType

The basic feature model is given by the gml:AbstractFeatureType, defined in the schema as follows:

```
<complexType name="AbstractFeatureType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGMLType">
      <sequence>
        <element ref="gml:boundedBy" minOccurs="0"/>
        <element ref="gml:location" minOccurs="0">
          <annotation>
            <appinfo>deprecated</appinfo>
            <documentation>deprecated in GML version 3.1</documentation>
          </annotation>
        </element>
      </sequence>
      <attribute name="fid" type="string">
        <annotation>
          <appinfo>deprecated</appinfo>
          <documentation>deprecated in GML version 3.0</documentation>
        </annotation>
      </attribute>
    </extension>
  </complexContent>
</complexType>
```

The content model for gml:AbstractFeatureType adds two specific properties suitable for geographic features to the content model defined in gml:AbstractGMLType. The value of the **gml:boundedBy** property describes an envelope that encloses the entire feature instance, and is primarily useful for supporting rapid searching for features that occur in a particular location.

*The value of the **gml:location** property describes the extent, position or relative location of the feature.*

*NOTE gml:location is deprecated as part of the standard content model of gml:AbstractFeatureType.*

*GML features also have a (optional) fid attribute. This is for backwards compatibility with GML 2 and is deprecated in GML 3.*

### 8.2.1.2 gml:\_Feature

The element gml:\_Feature is declared as follows:

```
<element name="_Feature" type="gml:AbstractFeatureType" abstract="true" substitutionGroup="gml:_GML"/>
```

This abstract element serves as the head of a substitution group which may contain any elements whose content model is derived from gml:AbstractFeatureType. This may be used as a variable in the construction of content models.

gml:\_Feature can be thought of as “anything that is a GML feature” and can be used to define variables or templates in which the value of a GML property is “any feature”. This occurs in particular in a GML Feature Collection (see 8.2.7) where the <gml:featureMember> and <gml:featureMembers> properties contain one or multiple copies of gml:\_Feature respectively.

## 8.2.2 Standard feature properties

### 8.2.2.1 gml:boundedBy, gml:BoundingShapeType, gml:EnvelopeWithTimePeriod , gml:EnvelopeWithTimePeriodType

This property describes the minimum bounding box or rectangle that encloses the entire feature. Its content model is as follows:

```
<element name="boundedBy" type="gml:BoundingShapeType"/>
<complexType name="BoundingShapeType">
  <sequence>
    <choice>
      <element ref="gml:Envelope"/>
      <element ref="gml:Null"/>
    </choice>
  </sequence>
</complexType>
```

The gml:Envelope element is defined in clause 9.1.5. A value of gml:Null may appear if an extent is not applicable or not available for some reason.

**NOTE** Since an envelope is defined simply by the positions of two diagonally opposing corners, the exact footprint of an envelope depends on the coordinate reference system used. If the feature being described has zero extent, then the two corners will coincide and the envelope has zero size. As for all properties, it is the responsibility of the data provider to ensure that the value is correct.

**NOTE** To provide backward compatibility with GML version 2, an additional element gml:Box is provided, with an identical content model and substitutable for gml:Envelope. This component is deprecated and should not be used in new applications.

For envelopes that include a temporal extent, gml:EnvelopeWithTimePeriod is provided, defined as follows:

```
<complexType name="EnvelopeWithTimePeriodType">
  <complexContent>
    <extension base="gml:EnvelopeType">
      <sequence>
        <element ref="gml:timePosition" minOccurs="2" maxOccurs="2"/>
      </sequence>
      <attribute name="frame" type="anyURI" use="optional" default="#ISO-8601"/>
    </extension>
  </complexContent>
</complexType>

<element name="EnvelopeWithTimePeriod" type="gml:EnvelopeWithTimePeriodType"
  substitutionGroup="gml:Envelope"/>
```

This adds two gml:timePosition properties which describe the extent of a time-envelope.

Since gml:EnvelopeWithTimePeriod is assigned to the substitution group headed by gml:Envelope, it may be used whenever gml:Envelope is valid.

**NOTE** In common with all geometry elements derived from gml:AbstractGeometryType (clause 9.1.2.1), the coordinate reference system used for the positions defining the gml:Envelope may be indicated using the optional XML attribute "srsName". If the coordinate reference system being used includes a time axis, then gml:Envelope can be used directly to describe a spatio-temporal extent.

### 8.2.2.2 gml:location, gml:LocationPropertyType, gml:LocationKeyword, gml:LocationString

The gml:location element is a convenience property that describes the generalized location of the feature. It is defined as follows:

```

<element name="location" type="gml:LocationPropertyType"/>
<complexType name="LocationPropertyType">
  <sequence >
    <choice>
      <element ref="gml:_Geometry"/>
      <element ref="gml:LocationKeyWord"/>
      <element ref="gml:LocationString"/>
      <element ref="gml:Null"/>
    </choice>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

The value of a location can be a geometry, a location string, a location keyword, or a null.

NOTE The flexible content model of the location property has proved to be difficult to implement in practice, so the element `gml:location` is deprecated in this version of GML.

A location string is text which should describe the location. It is declared as follows:

```
<element name="LocationString" type="gml:StringOrRefType"/>
```

The location keyword is a code usually selected from a controlled list. It is declared as follows:

```
<element name="LocationKeyWord" type="gml:CodeType"/>
```

EXAMPLE The following examples illustrate the different ways that the location property may appear in a data instance.

Location given as a `gml:Geometry` in a particular spatial reference system:

```

<gml:location>
  <gml:Point gml:id="point96" srsName="urn:EPSG:geographicCRS:62836405">
    <gml:pos>-31.936 115.834</gml:pos>
  </gml:Point>
</gml:location>

```

Location given using a name from a controlled source:

```

<gml:location>
  <gml:LocationKeyWord
    codeSpace="http://www.icsm.gov.au/icsm/cgna/index.html"
    >Leederville</gml:LocationKeyWord>
</gml:location>

```

Location given using a text string:

```

<gml:location>
  <gml:LocationString>Nigel Foster's town of residence</gml:LocationString>
</gml:location>

```

Location given by another service:

```
<gml:location xlink:href="http://www.ga.gov.au/bin/gazm01?placename=leederville&placetype=R&state=WA+"/>
```

### 8.2.2.3 `gml:priorityLocation`, `gml:priorityLocationType`

A property `gml:priorityLocation` is provided for GML Application Schema developers that wish to provide prioritized locations for their features. A `gml:priorityLocation` has the following content model:

```

<element name="priorityLocation" type="gml:PriorityLocationPropertyType"
  substitutionGroup="gml:location"/>

```

```

<complexType name="PriorityLocationPropertyType">
  <complexContent>
    <extension base="gml:LocationPropertyType">
      <attribute name="priority" type="string" use="optional"/>
    </extension>
  </complexContent>
</complexType>

```

Note that this simply adds a priority string to the base gml:location property. This can be used to assign levels of importance to the different locations (e.g. location by location string, geometry etc.).

NOTE The element gml:priorityLocation is deprecated in this version of GML.

#### 8.2.2.4 gml:featureProperty, gml:FeaturePropertyType, gml:featureMember

A particular class of properties define associations between features. These use the gml:AssociationType pattern as follows:

```

<complexType name="FeaturePropertyType">
  <sequence>
    <element ref="gml:_Feature" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

The concrete elements gml:featureMember and gml:featureProperty use this content model, and are declared as follows:

```

<element name="featureProperty" type="gml:FeaturePropertyType"/>
<element name="featureMember" type="gml:FeaturePropertyType"/>

```

#### 8.2.2.5 gml:featureMembers, gml:FeatureArrayPropertyType

At times it is useful to define a property containing an array of other features. This is done using a feature array property type as defined by the following content model:

```

<complexType name="FeatureArrayPropertyType">
  <sequence>
    <element ref="gml:_Feature" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</complexType>

```

The concrete elements gml:featureMembers uses this content model, and is declared as follows:

```

<element name="featureMembers" type="gml:FeatureArrayPropertyType"/>

```

### 8.2.3 Geometry Properties

In general the definition of feature properties is in the responsibility of the application schema designer. However, since the OGC abstract specification defines a limited set of basic geometry types, GML defines a set of predefined geometric property elements to associate instances of these geometry types with features.

The GML Feature schema also provides descriptive names for the geometry properties, encoded as common English language terms. Overall, there are three levels of naming geometry properties in GML:

**Formal names** that denote geometry properties in a manner based on the type of geometry allowed as a property value. These are names based on the name of the geometry type with a suffix "Property".

Table 1 Pre-defined formal geometry properties

Formal property name	XML Schema property type	Associated geometry object types (element names)
pointProperty	PointPropertyType	Point
curveProperty	CurvePropertyType	_Curve LineString Curve OrientableCurve CompositeCurve
surfaceProperty	SurfacePropertyType	_Surface Polygon Surface OrientableSurface CompositeSurface
solidProperty	SolidPropertyType	_Solid Solid CompositeSolid
multiPointProperty	MultiPointPropertyType	MultiPoint
multiCurveProperty	MultiCurvePropertyType	MultiCurve
multiSurfaceProperty	MultiSurfacePropertyType	MultiSurface
multiSolidProperty	MultiSolidPropertyType	MultiSolid
multiGeometryProperty	MultiGeometryPropertyType	MultiGeometry
pointArrayProperty	PointArrayPropertyType	Point(s)
curveArrayProperty	CurveArrayPropertyType	_Curve(s) LineString(s) Curve(s) OrientableCurve(s) CompositeCurve(s)
surfaceArrayProperty	SurfaceArrayPropertyType	_Surface(s) Polygon(s) Surface(s) OrientableSurface(s) CompositeSurface(s)
solidArrayProperty	SolidArrayPropertyType	_Solid(s) Solid(s) CompositeSolid(s)

The precise semantics of these geometry properties (e.g. "What does pointProperty of an object mean?") is not specified.

**Descriptive names** that provide a set of standardized synonyms or aliases defined in feature.xsd for the formal names; these allow use of a more user-friendly set of terms. These are:

```

<element name="centerOf" type="gml:PointPropertyType"/>
<element name="position" type="gml:PointPropertyType"/>
<element name="extentOf" type="gml:SurfacePropertyType"/>
<element name="edgeOf" type="gml:CurvePropertyType"/>
<element name="centerLineOf" type="gml:CurvePropertyType"/>

<element name="multiLocation" type="gml:MultiPointPropertyType"/>
<element name="multiCenterOf" type="gml:MultiPointPropertyType"/>
<element name="multiPosition" type="gml:MultiPointPropertyType"/>
<element name="multiCenterLineOf" type="gml:MultiCurvePropertyType"/>
<element name="multiEdgeOf" type="gml:MultiCurvePropertyType"/>
<element name="multiCoverage" type="gml:MultiSurfacePropertyType"/>
<element name="multiExtentOf" type="gml:MultiSurfacePropertyType"/>

```

These property elements provide common role names for the geometry of geographic features. The specific semantics of these role names (e.g. centerOf) is not defined in GML, and it is expected that additional clarification would be provided in <annotations> within the using GML application schema.

**Application-specific names** chosen by users and defined in application schemas based on GML.

There are no inherent restrictions in the type of geometry property a feature type may have. For example, a RadioTower feature type could have a *location* that returns a Point geometry to identify its location, and have another geometry property called *extentOf* that returns a Polygon geometry describing its physical structure, and have yet a third geometry property called *serviceArea* that returns a Polygon geometry describing the area in which its transmissions can be received reliably.

## 8.2.4 Topology Properties

In general the definition of topology properties is in the responsibility of the application schema designer. However, GML defines topology property elements that may be used to associate instances of topology types with features. All of these predefined topology property elements have formal names, so there are just two levels of naming topology properties in GML:

**Formal names** that denote geometry properties in a manner based on the type of topology allowed as a property value. Note that the first four of these properties express direction, whereas the others do not.

**Table 2 Pre-defined formal topology properties**

Formal property name	XML Schema property type	Associated topology object types (element names)
directedNode	DirectedNodePropertyType	Node
directedEdge	DirectedEdgePropertyType	Edge
directedFace	DirectedFacePropertyType	Face
directedTopoSolid	DirectedTopoSolidPropertyType	TopoSolid
topoPointProperty	TopoPointPropertyType	TopoPoint
topoCurveProperty	TopoCurvePropertyType	TopoCurve
topoSurfaceProperty	TopoSurfacePropertyType	TopoSurface
topoVolumeProperty	TopoVolumePropertyType	TopoVolume
topoComplexProperty	TopoComplexMemberType	TopoComplex

**Application-specific names** chosen by users and defined in application schemas based on GML.

There are no inherent restrictions of the type of topology property a feature type may have. For example, a StatisticalArea feature type could have one or more topoCurveProperty that returns a TopoCurve to represent

the boundary of the Statistical Area, and one or more topoSurfaceProperty that returns a TopoSurface to represent the Statistical Area itself.

### 8.2.5 Temporal Properties

#### 8.2.5.1 General purpose temporal properties

GML includes a small number of temporal property types that may be used in application schemas. Four (concrete) global elements representing time properties are provided for general use (compare with geometry properties described in clause 8.2.3):

gml:timePosition - for associating a direct time position with a feature or other object, encoded as a literal

gml:duration, gml:timeInterval - for associating a duration with a feature or other object

gml:validTime - for associating a time primitive with a feature or other object.

However, the temporal objects and the property types that refer to them provide a relatively comprehensive set of components for associating temporal information with features an other objects.

#### 8.2.5.2 Specific temporal properties

In general the definition of feature properties is in the responsibility of the application schema designer. Following the standard GML property model, the name of a property element should reflect the semantics of the relationship of the temporal object with the containing feature or other object. For example a feature type may have a *constructionTime* property whose XML type is “gml:TimePeriodPropertyType”, a *completionTime* property whose XML type is “gml:TimeInstantPropertyType”, and an *age* whose XML type is “gml:TimeDurationType” or “gml:TimeIntervalLengthType”. The following types are provided for direct use in declaring property elements:

XML Schema property type	Associated object types and substitutable object types
TimePrimitivePropertyType	_TimePrimitive, _TimeGeometricPrimitive, TimeInstant, TimePeriod, _TimeTopologyPrimitive, TimeEdge, TimeNode
TimeGeometricPrimitivePropertyType	_TimeGeometricPrimitive, TimeInstant, TimePeriod
TimeInstantPropertyType	TimeInstant
TimePeriodPropertyType	TimePeriod
TimeTopologyPrimitivePropertyType	_TimeTopologyPrimitive, TimeEdge, TimeNode
TimeEdgePropertyType	TimeEdge
TimeNodePropertyType	TimeNode
TimeTopologyComplexPropertyType	TimeTopologyComplex
TimeOrdinalEraPropertyType	TimeOrdinalEra
TimeCalendarPropertyType	TimeCalendar
TimeCalendarEraPropertyType	TimeCalendarEra

TimeClockPropertyType	TimeClock
-----------------------	-----------

## 8.2.6 Defining specific feature types

All specific feature types defined in application schemas shall be derived from `gml:AbstractFeatureType`, and thus all GML features inherit the optional `gml:boundedBy` and `gml:location` properties, as well as the standard `gml:metaDataProperty`, `gml:description` and `gml:name` properties inherited in turn from `gml:AbstractGMLType`, unless any property is suppressed in a derivation by restriction. `AbstractFeatureType` also inherits `gml:id` from `gml:AbstractGMLType` and this is the preferred means of supporting database identifiers in GML 3.

This type derivation requirement means that general purpose software designed to process arbitrary GML data shall be able to traverse the XML Schema derivation tree in order to determine whether or not a given element in the data stream is a GML feature.

A GML feature has a set of properties, where the specific set of properties defines the feature type. This follows the general definition of a feature given in ISO 19109, 19110 and the OGC Abstract Specification Topic 5. Properties have simple values, using XML Schema simpleContent types, or properties may have complex values, in which case they should be declared using the `gml:AssociationType` pattern described in Clause 7.5.3.

In the application schema defining a feature there shall be a global element declared whose name is the semantic type of the feature in the domain of discourse.

```
<element name="<<featureName>>" type = "<<contentModel >>" />
```

If that feature element may be used in a general `gml:FeatureCollection`, or in a feature collection defined by a different application schema, then its global element declaration shall be made a member of the `gml:_Feature` substitution group:

```
<element name="<<featureName>>" type = "<<contentModel >>" substitutionGroup="gml:_Feature" />
```

The content model of the feature may be a named (or anonymous) complex type.

### 8.2.6.1 gml:BoundedFeatureType

A simple restriction of `gml:AbstractFeatureType` makes the optional `boundedBy` property mandatory. `gml:BoundedFeatureType` is defined as follows:

```
<complexType name="BoundedFeatureType" abstract="true">
  <complexContent>
    <restriction base="gml:AbstractFeatureType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:location" minOccurs="0">
          <annotation>
            <appinfo>deprecated</appinfo>
            <documentation>deprecated in GML version 3.1</documentation>
          </annotation>
        </element>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

**NOTE** In XML Schema a content model derived by restriction must lead to a content model which is valid according to the base type – i.e. it is a valid subset of the parent. In the schema document this is expressed by copying down all the XML elements that are required for the content of the derived type, with their occurrence counts. In this instance the

adjustment made in the derived type is that an element that was optional in the parent (gml:boundedBy had minOccurs="0") is made mandatory (no occurrence constraints implies exactly one). Any element from the parent that is omitted (which can only be those with minOccurs="0" in the parent definition) is not inherited by the derived type. In contrast, it is not necessary to copy down the XML attributes, only those which are altered by restriction need be mentioned. By default the derived type has the same XML attributes and occurrence constraints as the parent. See XML Schema Part 1 (Structures) for more detail.

## 8.2.7 Feature Collections

A GML Feature Collection is a list of GML feature instances.

### 8.2.7.1 gml:AbstractFeatureCollectionType

GML feature collections shall be derived by extension or restriction from gml:AbstractFeatureCollectionType, defined as follows:

```
<complexType name="AbstractFeatureCollectionType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractFeatureType">
      <sequence>
        <element ref="gml:featureMember" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:featureMembers" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The gml:featureMember property (but not the gml:featureMembers property) follows the association pattern and can thus refer to a “remote” feature by means of the xlink:ref attribute.

The compositing property gml:featureMembers encloses a set of members of the Feature Collection regardless of their semantic type as features. gml:featureMember encloses or references a single feature instance. gml:featureMember and gml:featureMembers properties can appear on the same Feature Collection, but there can be only one gml:featureMembers property.

GML Feature Collections are themselves valid GML features and can have gml:location and other properties as defined in their GML Application Schema (see chapter 8.).

### 8.2.7.2 gml:\_FeatureCollection, gml:FeatureCollection, gml:FeatureCollectionType

```
<element name="_FeatureCollection" type="gml:AbstractFeatureCollectionType" abstract="true"
substitutionGroup="gml:_Feature"/>
```

This abstract element gml:\_FeatureCollection serves as the head of a substitution group which may contain any elements whose content model is derived from gml:AbstractFeatureType. This may be used as a variable in the construction of content models.

The schema also provides a concrete feature collection:

```
<element name="FeatureCollection" type="gml:FeatureCollectionType" substitutionGroup="gml:_Feature"/>

<complexType name="FeatureCollectionType">
  <complexContent>
    <extension base="gml:AbstractFeatureCollectionType"/>
  </complexContent>
</complexType>
```

Users of the concrete gml:FeatureCollection should note that it allows any valid GML feature as a member.

The content model of a GML Feature Collection shall be derived from `gml:AbstractFeatureCollectionType`. This in turn derives from `gml:AbstractFeatureType`. Hence feature collections are features, and are in general substitutable for `gml:_Feature`.

### 8.3 Spatial reference system used in a feature or feature collection

The value of the `gml:boundedBy` property for a feature or feature collection is usually a `gml:Envelope`. In common with all geometry elements derived from `gml:AbstractGeometryType` (clause 9.1.2.1), the coordinate reference system used for the positions defining the `gml:Envelope` may be indicated using the optional XML attribute “`srsName`”.

For convenience in constructing feature and feature collection instances, the value of the `srsName` attribute on the `gml:Envelope` (or `gml:Box`) which is the value of the `gml:boundedBy` property of the feature shall be inherited by all directly expressed geometries in all properties of the feature or members of the collection, unless overruled by the presence of a local `srsName`. Thus it is not necessary for a geometry to carry an `srsName` attribute if it uses the same coordinate reference system as given on the `gml:boundedBy` property of its parent feature. Inheritance of the coordinate reference system continues to any depth of nesting, but if overruled by a local `srsName` declaration, then the new coordinate reference system is inherited by all its children in turn.

Notwithstanding this rule, all the geometries used in a feature or feature collection may carry `srsName` attributes, in order to indicate the reference system used locally, even if they are the same as the parent.

## 9 GML schemas – basic geometry

### 9.1 General Concepts

#### 9.1.1 Overview

NOTE The geometry model of GML complies with ISO 19107. The underlying concepts of the types and elements of the GML geometry model are discussed in this document in more detail.

This clause describes the basic geometry model used by GML in the XML Schema documents:

- `geometryBasic0d1d.xsd`
- `geometryBasic2d.xsd`

The basic GML types and elements are described in the schemas listed in Annex C. The geometry schemas are identified by the following location-independent name (using URN syntax):

`urn:opengis:specification:gml:schema-xsd:geometryBasic0d1d:v3.1.0`  
`urn:opengis:specification:gml:schema-xsd:geometryBasic2d:v3.1.0`

All types, elements and attributes in these XML Schema documents are covered by this Clause.

NOTE The GML geometry model is complex. To make the schemas more accessible to readers with or without prior experience with GML 2, the different types and elements are grouped in several XML Schema documents.

Any geometry element that inherits the semantics of `AbstractGeometryType` can be viewed as a set of direct positions.

All of the classes derived from `AbstractGeometryType` inherit an optional association to a coordinate reference system. All direct positions shall directly or indirectly be associated with a coordinate reference system. When geometry elements are aggregated in another geometry element (such as a `MultiGeometry` or `GeometricComplex`), which already has a coordinate reference system specified, then these elements are assumed to be in that same coordinate reference system unless otherwise specified.

The geometry model distinguishes geometric primitives, aggregates and complexes.

Geometric primitives (i.e. instances of a subtype of AbstractGeometricPrimitiveType) will be open, that is, they will not contain their boundary points; curves will not contain their end points, surfaces will not contain their boundary curves, and solids will not contain their bounding surfaces.

## 9.1.2 Abstract Geometry

### 9.1.2.1 gml:AbstractGeometryType

```
<complexType name="AbstractGeometryType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGMLType">
      <attribute name="gid" type="string" use="optional" />
      <annotation>
        <appinfo>deprecated</appinfo>
        <documentation>deprecated in GML version 3.0</documentation>
      </annotation>
    </attribute>
    <attributeGroup ref="gml:SRSReferenceGroup"/>
  </extension>
</complexContent>
</complexType>
```

All geometry elements are derived directly or indirectly from this abstract supertype. A geometry element may have an identifying attribute ("gml:id"), a name (attribute "name") and a description (attribute "description"). It may be associated with a spatial reference system (attribute group "gml:SRSReferenceGroup").

The following rules shall be adhered to:

- Every geometry type shall derive from this abstract type.
- Every geometry element (i.e. an element of a geometry type) shall be directly or indirectly in the substitution group of \_Geometry.

*NOTE* The attribute "gid" is included for backward compatibility with GML 2 and is deprecated with GML 3. This identifier is superseded by "gml:id" inherited from AbstractGMLType. The attribute "gid" should not be used anymore and may be deleted in future versions of GML without further notice.

### 9.1.2.2 SRSReferenceGroup

```
<attributeGroup name="SRSReferenceGroup">
  <attribute name="srsName" type="anyURI" use="optional"/>
  <attribute name="srsDimension" type="positiveInteger" use="optional"/>
  <attributeGroup ref="gml:SRSInformationGroup"/>
</attributeGroup>
```

The attribute group "SRSReferenceGroup" is an optional reference to the CRS used by this geometry, with optional additional information to simplify the processing of the coordinates when a more complete definition of the CRS is not needed.

In general the attribute "srsName" points to a CRS instance of gml:CoordinateReferenceSystemType (see coordinateReferenceSystems.xsd). For well-known references it is not required that the CRS description exists at the location the URI points to.

If no srsName attribute is given, the CRS shall be specified as part of the larger context this geometry element is part of, e.g. a geometric aggregate.

NOTE The name "srsName" has been chosen deliberately. In the current version of GML "crsName" would be more appropriate, however, in future versions other types of spatial reference systems, i.e. those using geographic identifiers, may be supported by GML, too.

The optional attribute "srsDimension" is the length of coordinate sequence in a position. This dimension is derived from the coordinate reference system. When the "srsName" attribute is omitted, this attribute shall be omitted.

### 9.1.2.3 SRSInformationGroup

```
<attributeGroup name="SRSInformationGroup">
  <attribute name="axisLabels" type="gml:NCNameList" use="optional"/>
  <attribute name="uomLabels" type="gml:NCNameList" use="optional"/>
</attributeGroup>
```

The attributes "uomLabels" and "axisLabels", defined in the "SRSInformationGroup" attribute group, are optional additional and redundant information for a CRS to simplify the processing of the coordinate values when a more complete definition of the CRS is not needed. This information shall be the same as included in the complete definition of the CRS, referenced by the "srsName" attribute. When the "srsName" attribute is included, either both or neither of the "axisLabels" and "uomLabels" attributes shall be included. When the "srsName" attribute is omitted, both of these attributes shall be omitted.

The attribute "axisLabels" is an ordered list of labels for all the axes of this CRS. The "gml:axisAbbrev" value should be used for these axis labels, after spaces and forbidden characters are removed. When the "srsName" attribute is included, this attribute is optional. When the "srsName" attribute is omitted, this attribute shall also be omitted.

The attribute "uomLabels" is an ordered list of unit of measure (uom) labels for all the axes of this CRS. The value of the string in the "gml:catalogSymbol" should be used for this uom labels, after spaces and forbidden characters are removed. When the "axisLabels" attribute is included, this attribute shall also be included. When the "axisLabels" attribute is omitted, this attribute shall also be omitted.

### 9.1.2.4 gml:\_Geometry

```
<element name="_Geometry" type="gml:AbstractGeometryType" abstract="true" substitutionGroup="gml:_GML" />
```

The "\_Geometry" element is the abstract head of the substitution group for all geometry elements of GML 3. This includes pre-defined and user-defined geometry elements. Any geometry element shall be a direct or indirect extension/restriction of AbstractGeometryType and shall be directly or indirectly in the substitution group of "\_Geometry".

### 9.1.2.5 gml:GeometryPropertyType

```
<complexType name="GeometryPropertyType">
  <sequence>
    <element ref="gml:_Geometry" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A geometric property can either be any geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same or another document). Note that either the reference or the contained element shall be given, but not both or none. See clause 7.5.3.

If a feature has a property, which takes a geometry element as its value, this is called a geometry property. A generic type for such a geometry property is `GeometryPropertyType` which follows the general rules described in clauses 7.5.3.

### 9.1.2.6 gml:GeometryArrayPropertyType

```
<complexType name="GeometryArrayPropertyType">
  <sequence>
    <element ref="gml:_Geometry" minOccurs="0" maxOccurs="unbounded" />
  </sequence>
</complexType>
```

A container for an array of geometry elements. The elements are always contained in the array property, referencing geometry elements or arrays of geometry elements via XLinks is not supported.

If a feature has a property which takes an array of geometry elements as its value, this is called a geometry array property. A generic type for such a geometry property is `GeometryArrayPropertyType` which follows the general rules described in clause 7.5.3.

In general the elements in an array have to be homogenous, containing elements that are all of the same type. For example, all elements in a `GeometryArrayPropertyType` are of the type `AbstractGeometryType` (including types derived from this abstract base type) as long as the element is directly or indirectly substitutable for `gml:_Geometry`.

## 9.1.3 Coordinate Geometry

### 9.1.3.1 gml:DirectPositionType, gml:pos

```
<complexType name="DirectPositionType">
  <simpleContent>
    <extension base="gml:doubleList">
      <attributeGroup ref="gml:SRSReferenceGroup"/>
    </extension>
  </simpleContent>
</complexType>

<element name="pos" type="gml:DirectPositionType" />
```

`DirectPosition` instances hold the coordinates for a position within some coordinate reference system (CRS). Since `DirectPositions`, as data types, will often be included in larger objects (such as geometry elements) that have references to CRS, the "srsName" attribute will in general be missing, if this particular `DirectPosition` is included in a larger element with such a reference to a CRS. In this case, the CRS is implicitly assumed to take on the value of the containing object's CRS.

The attribute group "SRSReferenceGroup" is described in clause 9.1.2.2. If no srsName attribute is given, the CRS shall be specified as part of the larger context this geometry element is part of, e.g. a geometric element like point, curve, etc. It is expected that the attribute will be specified at the direct position level only in rare cases.

### 9.1.3.2 gml:DirectPositionListType, gml:posList

```
<complexType name="DirectPositionListType">
  <simpleContent>
    <extension base="gml:doubleList">
      <attributeGroup ref="gml:SRSReferenceGroup"/>
      <attribute name="count" type="positiveInteger" use="optional" />
    </extension>
  </simpleContent>
</complexType>
```

```
<element name="posList" type="gml:DirectPositionListType" />
```

posLists instances (and other instances with the content model specified by DirectPositionListType) hold the coordinates for a sequence of direct positions within the same coordinate reference system (CRS).

The attribute group "SRSReferenceGroup" is described in clause 9.1.2.2. If no srsName attribute is given, the CRS shall be specified as part of the larger context this geometry element is part of, e.g. a geometric element like point, curve, etc. It is expected that the attribute will be specified at the direct position level only in rare cases.

The optional attribute "count" allows to specify the number of direct positions in the list. If the attribute "count" is present then the attribute "srsDimension" shall be present, too.

The number of entries in the list is equal to the product of the dimensionality of the coordinate reference system (i.e. it is a derived value of the coordinate reference system definition) and the number of direct positions.

### 9.1.3.3 gml:geometricPositionGroup

```
<group name="geometricPositionGroup">
  <choice>
    <element ref="gml:pos"/>
    <element ref="gml:pointProperty"/>
  </choice>
</group>
```

GML supports two different ways to specify a geometric position: either by a direct position (a data type) or a point (a geometric object).

"pos" elements are positions that are "owned" by the geometric primitive encapsulating this geometric position.

"pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined elsewhere (reuse of existing points).

### 9.1.3.4 gml:geometricPositionListGroup

```
<group name="geometricPositionListGroup">
  <choice>
    <element ref="gml:posList"/>
    <group ref="gml:geometricPositionGroup" maxOccurs="unbounded"/>
  </choice>
</group>
```

GML supports two different ways to specify a list of geometric positions: either by a sequence of geometric positions (by reusing the group definition) or a sequence of direct positions (element "posList").

The "posList" element allows for a compact way to specify the coordinates of the positions, if all positions are represented in the same coordinate reference systems.

NOTE The definition of this group may be used as a pattern in the definition of geometric primitives instead of using this group definition directly. The main change will typically be a change in the multiplicity of the referenced group. A LineString, for example, requires at least two positions.

### 9.1.3.5 gml:CoordinatesType, gml:coordinates

```
<complexType name="CoordinatesType">
  <simpleContent>
    <extension base="string">
```

```

    <attribute name="decimal" type="string" default="." />
    <attribute name="cs" type="string" default="," />
    <attribute name="ts" type="string" default="&#x20;" />
  </extension>
</simpleContent>
</complexType>

<element name="coordinates" type="gml:CoordinatesType" />

```

This type is deprecated with GML version 3.1.0 for tuples with ordinate values that are numbers.

CoordinatesType is a text string, intended to be used to record an array of tuples or coordinates.

While it is not possible to enforce the internal structure of the string through schema validation, some optional attributes have been provided in previous versions of GML to support a description of the internal structure. These attributes are deprecated with GML version 3.1.0. The attributes are intended to be used as follows:

- decimal** symbol used for a decimal point  
(default="." a stop or period)
- cs** symbol used to separate components within a tuple or coordinate string  
(default="," a comma)
- ts** symbol used to separate tuples or coordinate strings  
(default=" " a space)

The "coordinates" element is deprecated with GML version 3.1.0.

Since it is based on the XML Schema string type, CoordinatesType can be used in the construction of tables of tuples or arrays of tuples, including ones that contain mixed text and numeric values. For example:

```
<my:tupleList>bettong,357.,2.3 skink,140.,0.75 wombat,770.,17.5</my:tupleList>
```

### 9.1.3.6 gml:CoordType, gml:coord

```

<complexType name="CoordType">
  <sequence>
    <element name="X" type="decimal" />
    <element name="Y" type="decimal" minOccurs="0" />
    <element name="Z" type="decimal" minOccurs="0" />
  </sequence>
</complexType>

```

Represents a coordinate tuple in one, two, or three dimensions. Deprecated with GML 3.0 and replaced by DirectPositionType.

```
<element name="coord" type="gml:CoordType" />
```

Deprecated with GML 3.0 and included for backwards compatibility with GML 2. Use the "pos" element instead.

## 9.1.4 Vectors

### 9.1.4.1 gml:VectorType, gml:Vector

```

<complexType name="VectorType">
  <simpleContent>
    <restriction base="gml:DirectPositionType"/>
  </simpleContent>
</complexType>

```

```
<element name="vector" type="gml:VectorType" />
```

A vector is an ordered set of numbers called coordinate that represent a position in space that is defined by a coordinate reference system (CRS). For some application the components of the position may be adjusted to yield a unit vector.

NOTE This definition allows VectorType to be used elsewhere when appropriate – e.g. for offsetVector in grids.xsd, and vector to be used directly when appropriate – e.g. in DirectionVector in direction.xsd.

## 9.1.5 Envelopes

### 9.1.5.1 gml:EnvelopeType, gml:Envelope

```
<complexType name="EnvelopeType">
  <choice>
    <sequence>
      <element name="lowerCorner" type="gml:DirectPositionType"/>
      <element name="upperCorner" type="gml:DirectPositionType"/>
    </sequence>
    <element ref="gml:coord" minOccurs="2" maxOccurs="2"/>
    <element ref="gml:pos" minOccurs="2" maxOccurs="2"/>
    <element ref="gml:coordinates"/>
  </choice>
  <attributeGroup ref="gml:SRSReferenceGroup"/>
</complexType>

<element name="Envelope" type="gml:EnvelopeType"/>
```

Envelope defines an extent using a pair of positions defining opposite corners in arbitrary dimensions. The first direct position is the "lower corner" (a coordinate position consisting of all the minimal ordinates for each dimension for all points within the envelope), the second one the "upper corner" (a coordinate position consisting of all the maximal ordinates for each dimension for all points within the envelope).

*The use of the properties "coord", "coordinates" and "pos" has been deprecated. The explicitly named properties "lowerCorner" and "upperCorner" shall be used instead.*

NOTE Regardless of dimension, an envelope can be represented without ambiguity as two direct positions (coordinate points) provided the ordering of those points adheres to the specified rule. Envelope is often referred to as a minimum bounding box or rectangle. However, this Envelope will not always specify the MINIMUM rectangular bounding region, if the referenced CRS is a Geographic CRS, or uses an Ellipsoidal, Spherical, Polar, or Cylindrical coordinate system, as those terms are specified in Subclause 12.4. Specifically, this Envelope will not specify the MINIMUM rectangular bounding region of a geometry whose set of points span the value discontinuity in an angular coordinate axis. Such axes include the Longitude and Latitude of Ellipsoidal and Spherical coordinate systems. That geometry could lie within a small region on the surface of the ellipsoid or sphere, or could extend completely around the ellipsoid or sphere.

## 9.2 Geometric Primitives

### 9.2.1 Simple Geometric Primitives (0- and 1-dimensional)

#### 9.2.1.1 gml:AbstractGeometricPrimitiveType, gml:\_GeometricPrimitive

```
<complexType name="AbstractGeometricPrimitiveType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGeometryType" />
  </complexContent>
</complexType>
```

This is the abstract root type of the geometric primitives. A geometric primitive is a geometric object that is not decomposed further into other primitives in the system. All primitives are oriented in the direction implied by the sequence of their coordinate tuples.

```
<element name="_GeometricPrimitive" type="gml:AbstractGeometricPrimitiveType" abstract="true"
substitutionGroup="gml:_Geometry" />
```

The "\_GeometricPrimitive" element is the abstract head of the substitution group for all (pre- and user-defined) geometric primitives.

```
<complexType name="GeometricPrimitivePropertyType">
  <sequence >
    <element ref="gml:_GeometricPrimitive" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a geometric primitive as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

### 9.2.1.2 gml:PointType, gml:Point

```
<complexType name="PointType">
  <complexContent>
    <extension base="gml:AbstractGeometricPrimitiveType">
      <sequence>
        <choice>
          <element ref="gml:pos" />
          <element ref="gml:coordinates" />
          <element ref="gml:coord">
            <annotation>
              <appinfo>deprecated</appinfo>
              <documentation>deprecated in GML version 3.0</documentation>
            </annotation>
          </element>
        </choice>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Point" type="gml:PointType" substitutionGroup="gml:_GeometricPrimitive" />
```

A Point is defined by a single coordinate tuple. The direct position of a point is specified by the "pos" element which is of type DirectPositionType.

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

### 9.2.1.3 gml:PointPropertyType, gml:pointProperty

```
<complexType name="PointPropertyType">
  <sequence >
    <element ref="gml:Point" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a point as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="pointProperty" type="gml:PointPropertyType" />
```

This property element either references a point via the XLink-attributes or contains the point element. pointProperty is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for Point.

#### 9.2.1.4 gml:PointArrayPropertyType, gml:pointArrayProperty

```
<complexType name="PointArrayPropertyType">
  <sequence>
    <element ref="gml:Point" minOccurs="0" maxOccurs="unbounded" />
  </sequence>
</complexType>
```

A container for an array of points. The elements are always contained in the array property, referencing geometry elements or arrays of geometry elements via XLinks is not supported.

```
<element name="pointArrayProperty" type="gml:PointArrayPropertyType" />
```

This property element contains a list of point elements. pointArrayProperty is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for a list of Points.

#### 9.2.1.5 gml:AbstractCurveType, gml:\_Curve

```
<complexType name="AbstractCurveType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGeometricPrimitiveType" />
  </complexContent>
</complexType>
```

An abstraction of a curve to support the different levels of complexity. The curve can always be viewed as a geometric primitive, i.e. is continuous.

```
<element name="_Curve" type="gml:AbstractCurveType" abstract="true"
  substitutionGroup="gml:_GeometricPrimitive" />
```

The "\_Curve" element is the abstract head of the substitution group for all (continuous) curve elements.

#### 9.2.1.6 gml:CurvePropertyType, gml:curveProperty

```
<complexType name="CurvePropertyType">
  <sequence>
    <element ref="gml:_Curve" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a curve as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="curveProperty" type="gml:CurvePropertyType" />
```

This property element either references a curve via the XLink-attributes or contains the curve element. curveProperty is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for \_Curve.

### 9.2.1.7 gml:CurveArrayPropertyType, gml:curveArrayProperty

```
<complexType name="CurveArrayPropertyType">
  <sequence>
    <element ref="gml:_Curve" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

A container for an array of curves. The elements are always contained in the array property, referencing geometry elements or arrays of geometry elements via XLinks is not supported.

```
<element name="curveArrayProperty" type="gml:CurveArrayPropertyType" />
```

This property element contains a list of curve elements. `curveArrayProperty` is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for a list of `_Curves`.

### 9.2.1.8 gml:LineStringType, gml:LineString

```
<complexType name="LineStringType">
  <complexContent>
    <extension base="gml:AbstractCurveType">
      <sequence>
        <choice>
          <choice minOccurs="2" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:coord">
              <annotation>
                <appinfo>deprecated</appinfo>
                <documentation>deprecated in GML version 3.0</documentation>
              </annotation>
            </element>
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```
<element name="LineString" type="gml:LineStringType" substitutionGroup="gml:_Curve" />
```

A `LineString` is a special curve that consists of a single segment with linear interpolation. It is defined by two or more coordinate tuples, with linear interpolation between them. It is backwards compatible with the `LineString` of GML 2. `GM_LineString` of ISO 19107 is implemented by `LineStringSegment`.

GML supports two different ways to specify the control points of a line string:

- A sequence of "pos" (`DirectPositionType`) or "pointProperty" (`PointPropertyType`) elements. "pos" elements are control points that are only part of this curve, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve only. The number of direct positions in the coordinates list shall be at least two and include the start and end point. Note that the start and end points of one line string are often identical with those of other line strings.

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.

### 9.2.1.9 **gml:LineStringPropertyType, gml:lineStringProperty**

```
<complexType name="LineStringPropertyType">
  <sequence>
    <element ref="gml:LineString" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

This type is deprecated with GML 3 and shall not be used. It is included for backwards compatibility with GML 2. Use *CurvePropertyType* instead.

A property that has a line string as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="lineStringProperty" type="gml:LineStringPropertyType" />
```

Deprecated with GML 3 and included only for backwards compatibility with GML 2. Use "curveProperty" instead.

This property element either references a line string via the XLink-attributes or contains the line string element.

## 9.2.2 Simple Geometric Primitives (2-dimensional)

### 9.2.2.1 **gml:AbstractSurfaceType, gml:\_Surface**

```
<complexType name="AbstractSurfaceType">
  <complexContent>
    <extension base="gml:AbstractGeometricPrimitiveType" />
  </complexContent>
</complexType>
```

An abstraction of a surface to support the different levels of complexity. A surface is always a continuous region of a plane.

```
<element name="_Surface" type="gml:AbstractSurfaceType" abstract="true"
substitutionGroup="gml:_GeometricPrimitive" />
```

The "\_Surface" element is the abstract head of the substitution group for all (continuous) surface elements.

### 9.2.2.2 **gml:SurfacePropertyType, gml:surfaceProperty**

```
<complexType name="SurfacePropertyType">
  <sequence>
    <element ref="gml:_Surface" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a surface as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="surfaceProperty" type="gml:SurfacePropertyType" />
```

This property element either references a surface via the XLink-attributes or contains the surface element. `surfaceProperty` is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for `_Surface`.

### 9.2.2.3 gml:SurfaceArrayType, gml:surfaceArrayProperty

```
<complexType name="SurfaceArrayType">
  <sequence>
    <element ref="gml:_Surface" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

A container for an array of surfaces. The elements are always contained in the array property, referencing geometry elements or arrays of geometry elements via XLinks is not supported.

```
<element name="surfaceArrayProperty" type="gml:SurfaceArrayType" />
```

This property element contains a list of surface elements. `surfaceArrayProperty` is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for a list of `_Surfaces`.

### 9.2.2.4 gml:PolygonType, gml:Polygon

```
<complexType name="PolygonType">
  <complexContent>
    <extension base="gml:AbstractSurfaceType">
      <sequence>
        <element ref="gml:exterior" minOccurs="0" />
        <element ref="gml:interior" minOccurs="0" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Polygon" type="gml:PolygonType" substitutionGroup="gml:_Surface" />
```

A Polygon is a special surface that is defined by a single surface patch. The boundary of this patch is coplanar and the polygon uses planar interpolation in its interior. It is backwards compatible with the Polygon of GML 2.

NOTE GM\_Polygon of ISO 19107 is implemented by PolygonPatch.

The elements "exterior" and "interior" describe the surface boundary of the polygon and are specified below.

### 9.2.2.5 gml:exterior, gml:interior, gml:outerBoundaryIs, gml:innerBoundaryIs

```
<element name="exterior" type="gml:AbstractRingPropertyType" />
```

A boundary of a surface consists of a number of rings. In the normal 2D case, one of these rings is distinguished as being the exterior boundary. In a general manifold this is not always possible, in which case all boundaries shall be listed as interior boundaries, and the exterior will be empty.

```
<element name="interior" type="gml:AbstractRingPropertyType" />
```

A boundary of a surface consists of a number of rings. The "interior" rings separate the surface / surface patch from the area enclosed by the rings.

```
<element name="outerBoundaryIs" type="gml:AbstractRingPropertyType" substitutionGroup="gml:exterior" />
```

*Deprecated with GML 3, included only for backwards compatibility with GML 2. Use "exterior" instead.*

```
<element name="innerBoundaryIs" type="gml:AbstractRingPropertyType" substitutionGroup="gml:interior" />
```

Deprecated with GML 3, included only for backwards compatibility with GML 2. Use "interior" instead.

### 9.2.2.6 gml:AbstractRingType, gml:\_Ring

```
<complexType name="AbstractRingType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGeometryType" />
  </complexContent>
</complexType>
```

An abstraction of a ring to support surface boundaries of different complexity.

```
<element name="_Ring" type="gml:AbstractRingType" abstract="true" />
```

The "\_Ring" element is the abstract head of the substitution group for all closed boundaries of a surface patch.

### 9.2.2.7 gml:AbstractRingPropertyType

```
<complexType name="AbstractRingPropertyType">
  <sequence>
    <element ref="gml:_Ring" />
  </sequence>
</complexType>
```

Encapsulates a ring to represent the surface boundary property of a surface.

### 9.2.2.8 gml:LinearRingType, gml:LinearRing

```
<complexType name="LinearRingType">
  <complexContent>
    <extension base="gml:AbstractRingType">
      <sequence>
        <choice>
          <choice minOccurs="4" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
          <element ref="gml:coord" minOccurs="4" maxOccurs="unbounded">
            <annotation>
              <appinfo>deprecated</appinfo>
              <documentation>deprecated in GML version 3.0</documentation>
            </annotation>
          </element>
        </choice>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="LinearRing" type="gml:LinearRingType" substitutionGroup="gml:_Ring" />
```

A LinearRing is defined by four or more coordinate tuples, with linear interpolation between them; the first and last coordinates shall be coincident.

GML supports two different ways to specify the control points of a linear ring:

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this ring, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this ring (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this ring only. The number of direct positions in the list shall be at least four.

The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.

The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.

### 9.2.2.9 gml:LinearRingPropertyType

```
<complexType name="LinearRingPropertyType">
  <choice>
    <element ref="gml:LinearRing" />
  </choice>
</complexType>
```

Encapsulates a ring to represent properties in features or geometry collections.

### 9.2.2.10 gml:PolygonPropertyType, gml:polygonProperty

```
<complexType name="PolygonPropertyType">
  <sequence>
    <element ref="gml:Polygon" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

This type is deprecated with GML 3 and shall not be used. It is included for backwards compatibility with GML 2. Use SurfacePropertyType instead.

A property that has a polygon as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="polygonProperty" type="gml:PolygonPropertyType" />
```

Deprecated with GML 3 and included only for backwards compatibility with GML 2. Use "surfaceProperty" instead.

This property element either references a polygon via the XLink-attributes or contains the polygon element.

## 10 GML schemas – more geometric primitives

### 10.1 Overview

Beside the "simple" geometric primitives specified in the previous chapter, this clause specifies additional primitives to describe real world situations which require a more expressive geometry model.

This clause describes these primitives in the XML Schema document

- geometryPrimitives.xsd.

The GML types and elements are described in the schemas listed in Annex C. The schema is identified by the following location-independent name (using URN syntax):

urn:opengis:specification:gml:schema-xsd:geometryPrimitives:v3.1.0

All types, elements and attributes in this XML Schema document is covered by this Clause.

## 10.2 Additional geometric primitives

### 10.2.1 1-dimensional geometric primitives

#### 10.2.1.1 gml:CurveType, gml:Curve

```
<complexType name="CurveType">
  <complexContent>
    <extension base="gml:AbstractCurveType">
      <sequence>
        <element ref="gml:segments" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Curve" type="gml:CurveType" substitutionGroup="gml:_Curve" />
```

Curve is a 1-dimensional primitive. Curves are continuous, connected, and have a measurable length in terms of the coordinate system.

A curve is composed of one or more curve segments. Each curve segment within a curve may be defined using a different interpolation method. The curve segments are connected to one another, with the end point of each segment except the last being the start point of the next segment in the segment list.

The orientation of the curve is positive.

The element "segments" encapsulates the segments of the curve.

#### 10.2.1.2 gml:AbstractCurveSegmentType, gml:\_CurveSegment

```
<complexType name="AbstractCurveSegmentType" abstract="true">
  <attribute name="numDerivativesAtStart" type="integer" use="optional" default="0" />
  <attribute name="numDerivativesAtEnd" type="integer" use="optional" default="0" />
  <attribute name="numDerivativeInterior" type="integer" use="optional" default="0" />
</complexType>
```

Curve segment defines a homogeneous segment of a curve.

The attribute "numDerivativesAtStart" specifies the type of continuity between this curve segment and its predecessor. If this is the first curve segment in the curve, one of these values, as appropriate, is ignored. The default value of "0" means simple continuity, which is a mandatory minimum level of continuity. This level is referred to as "C 0" in mathematical texts. A value of 1 means that the function and its first derivative are continuous at the appropriate end point: "C 1" continuity. A value of "n" for any integer means the function and its first n derivatives are continuous: "C n" continuity.

The attribute "numDerivativesAtEnd" specifies the type of continuity between this curve segment and its successor. If this is the last curve segment in the curve, one of these values, as appropriate, is ignored. The default value of "0" means simple continuity, which is a mandatory minimum level of continuity. This level is referred to as "C 0" in mathematical texts. A value of 1 means that the function and its first derivative are continuous at the appropriate end point: "C 1" continuity. A value of "n" for any integer means the function and its first n derivatives are continuous: "C n" continuity.

The attribute "numDerivativesInterior" specifies the type of continuity that is guaranteed interior to the curve. The default value of "0" means simple continuity, which is a mandatory minimum level of continuity. This level is referred to as "C 0" in mathematical texts. A value of 1 means that the function and its first derivative are continuous at the appropriate end point: "C 1" continuity. A value of "n" for any integer means the function and its first n derivatives are continuous: "C n" continuity.

**NOTE** Use of these attributes is only appropriate when the basic curve definition is an underdetermined system. For example, line string segments cannot support continuity above C 0, since there is no spare control parameter to adjust the incoming angle at the end points of the segment. Spline functions on the other hand often have extra degrees of freedom on end segments that allow them to adjust the values of the derivatives to support C 1 or higher continuity.

```
<element name="_CurveSegment" type="gml:AbstractCurveSegmentType" abstract="true" />
```

The "\_CurveSegment" element is the abstract head of the substitution group for all curve segment elements, i.e. continuous segments of the same interpolation mechanism.

### 10.2.1.3 gml:CurveSegmentArrayPropertyType, gml:segments

```
<complexType name="CurveSegmentArrayPropertyType">
  <sequence>
    <element ref="gml:_CurveSegment" minOccurs="0" maxOccurs="unbounded" />
  </sequence>
</complexType>
```

A container for an array of curve segments.

```
<element name="segments" type="gml:CurveSegmentArrayPropertyType" />
```

This property element contains a list of curve segments. The order of the elements is significant and shall be preserved when processing the array.

### 10.2.1.4 gml:CurveInterpolationType

```
<simpleType name="CurveInterpolationType">
  <restriction base="string">
    <enumeration value="linear" />
    <enumeration value="geodesic" />
    <enumeration value="circularArc3Points" />
    <enumeration value="circularArc2PointWithBulge" />
    <enumeration value="circularArcCenterPointWithRadius" />
    <enumeration value="elliptical" />
    <enumeration value="clothoid" />
    <enumeration value="conic" />
    <enumeration value="polynomialSpline" />
    <enumeration value="cubicSpline" />
    <enumeration value="rationalSpline" />
  </restriction>
</simpleType>
```

CurveInterpolationType is a list of codes that may be used to identify the interpolation mechanisms specified by an application schema.

### 10.2.1.5 gml:LineStringSegmentType, gml:LineStringSegment

```
<complexType name="LineStringSegmentType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <choice>
          <choice minOccurs="2" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
          </choice>
        </choice>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

        <element ref="gml:posList" />
        <element ref="gml:coordinates" />
    </choice>
</sequence>
<attribute name="interpolation" type="gml:CurveInterpolationType" fixed="linear" />
</extension>
</complexContent>
</complexType>

<element name="LineStringSegment" type="gml:LineStringSegmentType"
substitutionGroup="gml:_CurveSegment" />

```

A LineStringSegment is a curve segment that is defined by two or more coordinate tuples, with linear interpolation between them.

NOTE LineStringSegment implements GM\_LineString of ISO 19107.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only. The number of direct positions in the coordinate list shall be at least two and include the start and end point.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For a LineStringSegment the interpolation is fixed as "linear".

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.6 gml:ArcStringType, gml:ArcString

```

<complexType name="ArcStringType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <choice>
          <choice minOccurs="3" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
      </sequence>
      <attribute name="interpolation" type="gml:CurveInterpolationType" fixed="circularArc3Points" />
      <attribute name="numArc" type="integer" use="optional" />
    </extension>
  </complexContent>
</complexType>

<element name="ArcString" type="gml:ArcStringType" substitutionGroup="gml:_CurveSegment" />

```

An ArcString is a curve segment that uses three-point circular arc interpolation.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only. The number of direct positions in the coordinate list shall be at least three and include the start and end point.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For an ArcString the interpolation is fixed as "circularArc3Points".

The number of arcs in the arc string can be explicitly stated in the attribute "numArc". The number of control points in the arc string shall be  $2 * \text{numArc} + 1$ .

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.7 gml:ArcType, gml:Arc

```
<complexType name="ArcType">
  <complexContent>
    <restriction base="gml:ArcStringType">
      <sequence>
        <choice>
          <choice minOccurs="3" maxOccurs="3">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
      </sequence>
      <attribute name="numArc" type="integer" use="optional" fixed="1" />
    </restriction>
  </complexContent>
</complexType>

<element name="Arc" type="gml:ArcType" substitutionGroup="gml:ArcString" />
```

An Arc is an arc string with only one arc unit, i.e. three control points.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).

- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only. The number of direct positions in the coordinate list shall be three and include the start and end point.

An arc is an arc string consisting of a single arc, the attribute "numArc" is fixed to "1".

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.8 gml:CircleType, gml:Circle

```
<complexType name="CircleType">
  <complexContent>
    <extension base="gml:ArcType" />
  </complexContent>
</complexType>

<element name="Circle" type="gml:CircleType" substitutionGroup="gml:Arc" />
```

A Circle is an arc whose ends coincide to form a simple closed loop. The "start" and "end" bearing are equal and shall be the bearing for the first controlPoint listed. The three control points shall be distinct non-co-linear points for the Circle to be unambiguously defined. The arc is simply extended past the third control point until the first control point is encountered.

#### 10.2.1.9 gml:ArcStringByBulgeType, gml:ArcStringByBulge

```
<complexType name="ArcStringByBulgeType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <choice>
          <choice minOccurs="2" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
        <element name="bulge" type="gml:double" maxOccurs="unbounded"/>
        <element name="normal" type="gml:VectorType" maxOccurs="unbounded" />
      </sequence>
      <attribute name="interpolation" type="gml:CurveInterpolationType"
        fixed="circularArc2PointWithBulge" />
      <attribute name="numArc" type="integer" use="optional" />
    </extension>
  </complexContent>
</complexType>

<element name="ArcStringByBulge" type="gml:ArcStringByBulgeType" substitutionGroup="gml:_CurveSegment" />
```

This variant of the arc computes the mid points of the arcs instead of storing the coordinates directly. The control point sequence consists of the start and end points of each arc plus the bulge.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain

a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).

- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only. The number of direct positions in the coordinate list shall be at least two and include the start and end point.

The element "bulge" controls the offset of each arc's midpoint. The "bulge" is the real number multiplier for the normal that determines the offset direction of the midpoint of each arc. The length of the bulge sequence is exactly 1 less than the length of the control point array, since a bulge is needed for each pair of adjacent points in the control point array. The bulge is not given by a distance, since it is simply a multiplier for the normal.

The midpoint of the resulting arc is given by:  $\text{midPoint} = ((\text{startPoint} + \text{endPoint})/2.0) + \text{bulge} * \text{normal}$ .

The element "normal" is a vector normal (perpendicular) to the chord of the arc, the line joining the first and last point of the arc. In a 2D coordinate system, there are only two possible directions for the normal, and it is often given as a signed real, indicating its length, with a positive sign indicating a left turn angle from the chord line, and a negative sign indicating a right turn from the chord. In 3D, the normal determines the plane of the arc, along with the start and endPoint of the arc.

The normal is usually a unit vector, but this is not absolutely necessary. If the normal is a zero vector, the geometric object becomes equivalent to the straight line between the two end points. The length of the normal sequence is exactly the same as for the bulge sequence, 1 less than the control point sequence length.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For an ArcStringByBulge the interpolation is fixed as "circularArc2PointWithBulge".

The number of arcs in the arc string can be explicitly stated in the attribute "numArc". The number of control points in the arc string shall be numArc + 1.

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.10 gml:ArcByBulgeType, gml:ArcByBulge

```
<complexType name="ArcByBulgeType">
  <complexContent>
    <restriction base="gml:ArcStringByBulgeType">
      <sequence>
        <choice>
          <choice minOccurs="2" maxOccurs="2">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
        <element name="bulge" type="gml:double" />
        <element name="normal" type="gml:VectorType"/>
      </sequence>
      <attribute name="numArc" type="integer" use="optional" fixed="1" />
    </restriction>
  </complexContent>
</complexType>
```

```
<element name="ArcByBulge" type="gml:ArcByBulgeType" substitutionGroup="gml:ArcStringByBulge" />
```

An ArcByBulge is an arc string with only one arc unit, i.e. two control points and one bulge.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only. The number of direct positions in the coordinate list shall be two and include the start and end point.

The element "bulge" controls the offset of each arc's midpoint. The "bulge" is the real number multiplier for the normal that determines the offset direction of the midpoint of each arc. The length of the bulge sequence is exactly 1 less than the length of the control point array, since a bulge is needed for each pair of adjacent points in the control point array. The bulge is not given by a distance, since it is simply a multiplier for the normal.

The midpoint of the resulting arc is given by:  $\text{midPoint} = ((\text{startPoint} + \text{endPoint})/2.0) + \text{bulge} * \text{normal}$ .

For an Arc there is exactly one bulge.

The element "normal" is a vector normal (perpendicular) to the chord of the arc, the line joining the first and last point of the arc. In a 2D coordinate system, there are only two possible directions for the normal, and it is often given as a signed real, indicating its length, with a positive sign indicating a left turn angle from the chord line, and a negative sign indicating a right turn from the chord. In 3D, the normal determines the plane of the arc, along with the start and endPoint of the arc.

The normal is usually a unit vector, but this is not absolutely necessary. If the normal is a zero vector, the geometric object becomes equivalent to the straight line between the two end points. The length of the normal sequence is exactly the same as for the bulge sequence, 1 less than the control point sequence length.

For an Arc there is exactly one normal vector.

An arc is an arc string consisting of a single arc, the attribute "numArc" is fixed to "1".

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.11 gml:ArcByCenterPointType, gml:ArcByCenterPoint

```
<complexType name="ArcByCenterPointType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <choice>
          <choice>
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
      </sequence>
      <element name="radius" type="gml:LengthType" />
    </extension>
  </complexContent>
</complexType>
```

```

        <element name="startAngle" type="gml:AngleType" minOccurs="0" />
        <element name="endAngle" type="gml:AngleType" minOccurs="0" />
    </sequence>
    <attribute name="interpolation" type="gml:CurveInterpolationType"
        fixed="circularArcCenterPointWithRadius" />
    <attribute name="numArc" type="integer" use="required" fixed="1" />
</extension>
</complexContent>
</complexType>

<element name="ArcByCenterPoint" type="gml:ArcByCenterPointType" substitutionGroup="gml:_CurveSegment" />

```

This variant of the arc requires that the points on the arc have to be computed instead of storing the coordinates directly. The control point is the center point of the arc plus the radius and the bearing at start and end. This representation can be used only in 2D.

GML supports two different ways to specify the control points of a curve segment.

- A "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) element. The "pos" element contains a center point that is only part of this curve segment, a "pointProperty" element contains a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element can be used to specify the coordinates of the center point, too. The number of direct positions in the coordinate list shall be one.

The element "radius" specifies the radius of the arc.

The element "startAngle" specifies the bearing of the arc at the start.

The element "endAngle" specifies the bearing of the arc at the end.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For an ArcByCenterPoint the interpolation is fixed as "circularArcCenterPointWithRadius".

Since this type describes always a single arc, the attribute "numArc" is fixed to "1".

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.12 gml:CircleByCenterPointType, gml:CircleByCenterPoint

```

<complexType name="CircleByCenterPointType">
    <complexContent>
        <extension base="gml:ArcByCenterPointType" />
    </complexContent>
</complexType>

<element name="CircleByCenterPoint" type="gml:CircleByCenterPointType"
    substitutionGroup="gml:ArcByCenterPoint" />

```

A CircleByCenterPoint is an ArcByCenterPoint with identical start and end angle to form a full circle. Again, this representation can be used only in 2D.

#### 10.2.1.13 gml:CubicSplineType, gml:CubicSpline

```

<complexType name="CubicSplineType">

```

```

<complexContent>
  <extension base="gml:AbstractCurveSegmentType">
    <sequence>
      <choice>
        <choice minOccurs="2" maxOccurs="unbounded">
          <element ref="gml:pos" />
          <element ref="gml:pointProperty" />
          <element ref="gml:pointRep" />
        </choice>
        <element ref="gml:posList" />
        <element ref="gml:coordinates" />
      </choice>
      <element name="vectorAtStart" type="gml:VectorType" />
      <element name="vectorAtEnd" type="gml:VectorType" />
    </sequence>
    <attribute name="interpolation" type="gml:CurveInterpolationType" fixed="cubicSpline" />
    <attribute name="degree" type="integer" fixed="3" />
  </extension>
</complexContent>
</complexType>

<element name="CubicSpline" type="gml:CubicSplineType" substitutionGroup="gml:_CurveSegment" />

```

Cubic splines are similar to line strings in that they are a sequence of segments each with its own defining function. A cubic spline uses the control points and a set of derivative parameters to define a piecewise 3rd degree polynomial interpolation. Unlike line-strings, the parameterization by arc length is not necessarily still a polynomial.

The function describing the curve shall be C2, that is, have a continuous 1st and 2nd derivative at all points, and pass through the controlPoints in the order given. Between the control points, the curve segment is defined by a cubic polynomial. At each control point, the polynomial changes in such a manner that the 1st and 2nd derivative vectors are the same from either side. The control parameters record shall contain vectorAtStart, and vectorAtEnd which are the unit tangent vectors at controlPoint[1] and controlPoint[n] where n = controlPoint.count.

NOTE Only the direction of the vectors is relevant, not their length.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only. The number of direct positions in the coordinate list shall be at least three and include the start and end point.

The element "vectorAtStart" is the unit tangent vector at the start point of the spline.

The element "vectorAtEnd" is the unit tangent vector at the end point of the spline.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For a CubicSpline the interpolation is fixed as "cubicSpline".

The attribute "degree" shall be the degree of the polynomial used for interpolation in this spline. Therefore the degree for a cubic spline is fixed to "3".

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.

#### 10.2.1.14 gml:BSplineType, gml:BSpline

```

<complexType name="BSplineType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <choice>
          <choice minOccurs="0" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
          <element ref="gml:coordinates" />
        </choice>
        <element name="degree" type="nonNegativeInteger" />
        <element name="knot" type="gml:KnotPropertyType" minOccurs="2" maxOccurs="unbounded" />
      </sequence>
      <attribute name="interpolation" type="gml:CurveInterpolationType" default="polynomialSpline" />
      <attribute name="isPolynomial" type="boolean" use="optional" />
      <attribute name="knotType" type="gml:KnotTypesType" use="optional" />
    </extension>
  </complexContent>
</complexType>

<element name="BSpline" type="gml:BSplineType" substitutionGroup="gml:_CurveSegment" />

```

A B-Spline is a piecewise parametric polynomial or rational curve described in terms of control points and basis functions. Knots are breakpoints on the curve that connect its pieces.

They are given as a non-decreasing sequence of real numbers. If the weights in the knots are equal then it is a polynomial spline. The degree is the algebraic degree of the basis functions.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only.

The property element "degree" shall be the degree of the polynomial used for interpolation in this spline.

The property element "knot" shall be the sequence of distinct knots used to define the spline basis functions.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For a BSpline the interpolation can be either "polynomialSpline" or "rationalSpline", default is "polynomialSpline".

The attribute "isPolynomial" is set to "true" if this is a polynomial spline.

The attribute "knotType" gives the type of knot distribution used in defining this spline. This is for information only and is set according to the different construction-functions.

The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.

The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.

#### 10.2.1.15 gml:KnotType, gml:KnotPropertyType

```
<complexType name="KnotType">
  <sequence>
    <element name="value" type="double" />
    <element name="multiplicity" type="nonNegativeInteger" />
    <element name="weight" type="double" />
  </sequence>
</complexType>
```

A knot is a breakpoint on a piecewise spline curve.

The property element "value" is the value of the parameter at the knot of the spline. The sequence of knots shall be a non-decreasing sequence. That is, each knot's value in the sequence shall be equal to or greater than the previous knot's value. The use of equal consecutive knots is normally handled using the multiplicity.

The property element "multiplicity" is the multiplicity of this knot used in the definition of the spline (with the same weight).

The property element "weight" is the value of the averaging weight used for this knot of the spline.

```
<complexType name="KnotPropertyType">
  <sequence>
    <element name="Knot" type="gml:KnotType" />
  </sequence>
</complexType>
```

Encapsulates a knot to use it in a geometric type.

#### 10.2.1.16 gml:KnotTypesType

```
<simpleType name="KnotTypesType">
  <restriction base="string">
    <enumeration value="uniform" />
    <enumeration value="quasiUniform" />
    <enumeration value="piecewiseBezier" />
  </restriction>
</simpleType>
```

Defines allowed values for the knots` type. Uniform knots implies that all knots are of multiplicity 1 and they differ by a positive constant from the preceding knot. Knots are quasi-uniform if they are of multiplicity (degree + 1) at the ends, of multiplicity 1 elsewhere, and they differ by a positive constant from the preceding knot.

#### 10.2.1.17 gml:BezierType, gml:Bezier

```
<complexType name="BezierType">
  <complexContent>
    <restriction base="gml:BSplineType">
      <sequence>
        <choice>
          <choice minOccurs="0" maxOccurs="unbounded">
            <element ref="gml:pos" />
            <element ref="gml:pointProperty" />
            <element ref="gml:pointRep" />
          </choice>
          <element ref="gml:posList" />
        </choice>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

```

        <element ref="gml:coordinates" />
    </choice>
    <element name="degree" type="nonNegativeInteger" />
    <element name="knot" type="gml:KnotPropertyType" minOccurs="2" maxOccurs="2" />
</sequence>
<attribute name="interpolation" type="gml:CurveInterpolationType" fixed="polynomialSpline" />
<attribute name="isPolynomial" type="boolean" fixed="true" />
<attribute name="knotType" type="gml:KnotTypesType" use="prohibited" />
</restriction>
</complexContent>
</complexType>

<element name="Bezier" type="gml:BezierType" substitutionGroup="gml:BSpline" />

```

Bezier curves are polynomial splines that use Bezier or Bernstein polynomials for interpolation purposes. It is a special case of the B-Spline curve with two knots.

GML supports two different ways to specify the control points of a curve segment.

- A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).
- The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only.

The property element "degree" shall be the degree of the polynomial used for interpolation in this spline.

The property element "knot" shall be the sequence of distinct knots used to define the spline basis functions.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For a Bezier the interpolation is fixed as "polynomialSpline".

The attribute "isPolynomial" shall be "true" as this is a polynomial spline.

The property "knotType" is not relevant for Bezier curve segments.

*The use of the element "coordinates" is deprecated with GML version 3.1.0. Use "posList" instead.*

*The use of the elements "coord" is deprecated. Use "pos" instead, the element is included only for backwards compatibility with previous versions of GML.*

#### 10.2.1.18 gml:OrientableCurveType, gml:OrientableCurve, gml:baseCurve

```

<complexType name="OrientableCurveType">
  <complexContent>
    <extension base="gml:AbstractCurveType">
      <sequence>
        <element ref="gml:baseCurve" />
      </sequence>
      <attribute name="orientation" type="gml:SignType" default="+" />
    </extension>
  </complexContent>
</complexType>

<element name="baseCurve" type="gml:CurvePropertyType" />

<element name="OrientableCurve" type="gml:OrientableCurveType" substitutionGroup="gml:_Curve" />

```

OrientableCurve consists of a curve and an orientation. If the orientation is "+", then the OrientableCurve is identical to the baseCurve. If the orientation is "-", then the OrientableCurve is related to another \_Curve with a parameterization that reverses the sense of the curve traversal.

The element "baseCurve" references or contains the base curve. The property "baseCurve" either references the base curve via the XLink-attributes or contains the curve element. A curve element is any element which is substitutable for "\_Curve". The base curve has positive orientation.

NOTE This definition allows for a nested structure, i.e. an OrientableCurve may use another OrientableCurve as its base curve.

If the attribute "orientation" is "+", then the OrientableCurve is identical to the baseCurve. If the orientation is "-", then the OrientableCurve is related to another \_Curve with a parameterization that reverses the sense of the curve traversal. "+" is the default value.

### 10.2.1.19 gml:OffsetCurveType, gml:OffsetCurve

```
<complexType name="OffsetCurveType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <element name="offsetBase" type="gml:CurvePropertyType"/>
        <element name="distance" type="gml:LengthType"/>
        <element name="refDirection" type="gml:VectorType" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="OffsetCurve" type="gml:OffsetCurveType" substitutionGroup="gml:_CurveSegment"/>
```

An offset curve is a curve at a constant distance from the basis curve. Offsets can be useful as cheap and simple alternatives to constructing curves that are offsets by definition.

OffsetBase is a reference to the curve from which this curve is defined as an offset.

Distance is the distance at which the offset curve is generated from the basis curve. In 2D systems, positive distances are to be to the left of the basis curve, and the negative distances are to be to the right of the basis curve.

refDistance is used to define the vector direction of the offset curve from the basis curve. It can be omitted in the 2D case, where the distance can be positive or negative. In that case, distance defines left side (positive distance) or right side (negative distance) with respect to the tangent to the basis curve.

In 3D, the basis curve shall have a well defined tangent direction for every point. The offset curve at any point in 3D, the basis curve shall have a well-defined tangent direction for every point. The offset curve at any point (parameter) on the basis curve "c" is in the direction

$$\vec{s} = \vec{v} \times \vec{t} \quad \text{where} \quad \vec{v} = c.refDirection() \quad \text{and} \quad \vec{t} = c.tangent()$$

For the offset direction to be well-defined, v shall not on any point of the curve be in the same, or opposite, direction as t.

The default value of the refDirection shall be the local co-ordinate axis vector for elevation, which indicates up for the curve in a geographic sense.

NOTE If the refDirection is the positive tangent to the local elevation axis ("points upward"), then the offset vector points to the left of the curve when viewed from above.

### 10.2.1.20 gml:AffinePlacementType, gml:AffinePlacement

```

<complexType name="AffinePlacementType">
  <sequence>
    <element name="location" type="gml:DirectPositionType"/>
    <element name="refDirection" type="gml:VectorType" maxOccurs="unbounded"/>
    <element name="inDimension" type="positiveInteger"/>
    <element name="outDimension" type="positiveInteger"/>
  </sequence>
</complexType>

<element name="AffinePlacement" type="AffinePlacementType"/>

```

A placement takes a standard geometric construction and places it in geographic space. It defines a transformation from a constructive parameter space to the co-ordinate space of the co-ordinate reference system being used. Parameter spaces in formulae in this International Standard are given as  $(u, v)$  in 2D and  $(u, v, w)$  in 3D. Co-ordinate reference systems positions are given in formulae, in this International Standard, by either  $(x, y)$  in 2D, or  $(x, y, z)$  in 3D.

Affine placements are defined by linear transformations from parameter space to the target co-ordinate space. 2-dimensional Cartesian parameter space,  $(u, v)$  transforms into 3-dimensional co-ordinate reference systems  $(x, y, z)$  by using an affine transformation,  $(u, v) \rightarrow (x, y, z)$  which is defined:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} u_x & v_x \\ u_y & v_y \\ u_z & v_z \end{bmatrix} \begin{bmatrix} u \\ v \end{bmatrix} + \begin{bmatrix} x_0 \\ y_0 \\ z_0 \end{bmatrix}$$

Then, given this equation, the location element of the AffinePlacement is the direct position  $(x_0, y_0, z_0)$ , which is the target position of the origin in  $(u, v)$ . The two reference directions  $(u_x, u_y, u_z)$  and  $(v_x, v_y, v_z)$  are the target directions of the unit vectors at the origin in  $(u, v)$ .

The "location" property gives the target of the parameter space origin. This is the vector  $(x_0, y_0, z_0)$  in the formulae above.

The attribute "refDirection" gives the target directions for the co-ordinate basis vectors of the parameter space. These are the columns of the matrix in the formulae given above. The number of directions given shall be inDimension. The dimension of the directions shall be outDimension.

### 10.2.1.21 gml:ClothoidType, gml:Clothoid

```

<complexType name="ClothoidType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <element name="refLocation">
          <complexType>
            <sequence>
              <element ref="gml:AffinePlacement"/>
            </sequence>
          </complexType>
        </element>
        <element name="scaleFactor" type="decimal"/>
        <element name="startParameter" type="double"/>
        <element name="endParameter" type="double"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Clothoid" type="gml:ClothoidType" substitutionGroup="gml:_CurveSegment"/>

```

A clothoid, or Cornu's spiral, is plane curve whose curvature is a fixed function of its length. In suitably chosen co-ordinates it is given by Fresnel's integrals:

$$x(t) = \int_0^t \cos\left(\frac{A\tau^2}{2}\right) d\tau \quad \text{and} \quad y(t) = \int_0^t \sin\left(\frac{A\tau^2}{2}\right) d\tau$$

This geometry is mainly used as a transition curve between curves of type straight line to circular arc or circular arc to circular arc. With this curve type it is possible to achieve a C2-continuous transition between the above mentioned curve types. One formula for the clothoid is  $A \cdot A = R \cdot t$  where  $A$  is a constant,  $R$  is the varying radius of curvature along the curve and  $t$  is the length along the curve and given in the Fresnel integrals.

The "refLocation" is an affine mapping that places the curve defined by the Fresnel Integrals into the co-ordinate reference system of this object.

The startParameter is the arc length distance from the inflection point that will be the start point for this curve segment. This shall be lower limit used in the Fresnel integral and is the value of the constructive parameter of this curve segment at its start point. The startParameter can either be positive or negative.

NOTE If 0.0 (zero), lies between the startParameter and the endParameter of the clothoid, then the curve goes through the clothoid's inflection point, and the direction of its radius of curvature, given by the second derivative vector, changes sides with respect to the tangent vector. The term "length" distance for the parameter "t" is applicable only in the parameter space and its relation to arc length after use of the placement, and with respect to the co-ordinate reference system of the curve is not deterministic.

The endParameter is the arc length distance from the inflection point that will be the end point for this curve segment. This shall be upper limit used in the Fresnel integral and is the value of the constructive parameter of this curve segment at its start point. The startParameter can either be positive or negative.

#### 10.2.1.22 gml:GeodesicStringType, gml:GeodesicString

```
<complexType name="GeodesicStringType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <choice>
        <element ref="gml:posList"/>
        <group ref="gml:geometricPositionGroup" minOccurs="2" maxOccurs="unbounded"/>
      </choice>
      <attribute name="interpolation" type="gml:CurveInterpolationType" fixed="geodesic">
    </extension>
  </complexContent>
</complexType>

<element name="GeodesicString" type="gml:GeodesicStringType" substitutionGroup="gml:_CurveSegment"/>
```

A GeodesicString consists of sequence of geodesic segments. The type essentially combines a sequence of Geodesic into a single object. The GeodesicString is computed from two or more positions and an interpolation using geodesics defined from the geoid (or ellipsoid) of the co-ordinate reference system being used.

GML supports two different ways to specify the control points of a curve segment.

A sequence of "pos" (DirectPositionType) or "pointProperty" (PointPropertyType) elements. "pos" elements are control points that are only part of this curve segment, "pointProperty" elements contain a point that may

be referenced from other geometry elements or reference another point defined outside of this curve segment (reuse of existing points).

The "posList" element allows for a compact way to specify the coordinates of the control points, if all control points are in the same coordinate reference systems and belong to this curve segment only.

The number of direct positions in the list shall be at least two.

The attribute "interpolation" specifies the curve interpolation mechanism used for this segment. This mechanism uses the control points and control parameters to determine the position of this curve segment. For an GeodesicString the interpolation is fixed as "geodesic".

### 10.2.1.23 gml:GeodesicType, gml:Geodesic

```
<complexType name="GeodesicType">
  <complexContent>
    <extension base="gml:GeodesicStringType"/>
  </complexContent>
</complexType>

<element name="Geodesic" type="gml:GeodesicType" substitutionGroup="gml:GeodesicString"/>
```

A Geodesic consists of two distinct positions joined by a geodesic curve. The control points of a Geodesic shall lie on the geodesic between its start point and end points. Between these two points, a geodesic curve defined from ellipsoid or geoid model used by the co-ordinate reference systems may be used to interpolate other positions. Any other point in the controlPoint array shall fall on this geodesic.

## 10.2.2 2-dimensional geometric primitives

### 10.2.2.1 gml:SurfaceType, gml:Surface

```
<complexType name="SurfaceType">
  <complexContent>
    <extension base="gml:AbstractSurfaceType">
      <sequence>
        <element ref="gml:patches" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Surface" type="gml:SurfaceType" substitutionGroup="gml:_Surface" />
```

A Surface is a 2-dimensional primitive and is composed of one or more surface patches. The surface patches are connected to one another.

The orientation of the surface is positive ("up"). The orientation of a surface chooses an "up" direction through the choice of the upward normal, which, if the surface is not a cycle, is the side of the surface from which the exterior boundary appears counterclockwise. Reversal of the surface orientation reverses the curve orientation of each boundary component, and interchanges the conceptual "up" and "down" direction of the surface. If the surface is the boundary of a solid, the "up" direction is usually outward. For closed surfaces, which have no boundary, the up direction is that of the surface patches, which shall be consistent with one another. Its included surface patches describe the interior structure of the Surface.

The element "patches" encapsulates the patches of the surface.

### 10.2.2.2 gml:AbstractSurfacePatchType, gml :\_SurfacePatch

```
<complexType name="AbstractSurfacePatchType" abstract="true" />
```

A surface patch defines a homogenous portion of a surface.

```
<element name="_SurfacePatch" type="gml:AbstractSurfacePatchType" abstract="true" />
```

The "\_SurfacePatch" element is the abstract head of the substitution group for all surface patch elements describing a continuous portion of a surface.

### 10.2.2.3 gml:SurfacePatchArrayPropertyType, gml:patches

```
<complexType name="SurfacePatchArrayPropertyType">
  <sequence>
    <element ref="gml:_SurfacePatch" minOccurs="0" maxOccurs="unbounded" />
  </sequence>
</complexType>
```

A container for an array of surface patches.

```
<element name="patches" type="gml:SurfacePatchArrayPropertyType" />
```

This property element contains a list of surface patches. The order of the elements is significant and shall be preserved when processing the array.

### 10.2.2.4 gml:SurfaceInterpolationType

```
<simpleType name="SurfaceInterpolationType">
  <restriction base="string">
    <enumeration value="none" />
    <enumeration value="planar" />
    <enumeration value="spherical" />
    <enumeration value="elliptical" />
    <enumeration value="conic" />
    <enumeration value="tin" />
    <enumeration value="parametricCurve" />
    <enumeration value="polynomialSpline" />
    <enumeration value="rationalSpline" />
    <enumeration value="triangulatedSpline" />
  </restriction>
</simpleType>
```

SurfaceInterpolationType is a list of codes that may be used to identify the interpolation mechanisms specified by an application schema.

### 10.2.2.5 gml:PolygonPatchType

```
<complexType name="PolygonPatchType">
  <complexContent>
    <extension base="gml:AbstractSurfacePatchType">
      <sequence>
        <element ref="gml:exterior" minOccurs="0" />
        <element ref="gml:interior" minOccurs="0" maxOccurs="unbounded" />
      </sequence>
      <attribute name="interpolation" type="gml:SurfaceInterpolationType" fixed="planar" />
    </extension>
  </complexContent>
</complexType>

<element name="PolygonPatch" type="gml:PolygonPatchType" substitutionGroup="gml:_SurfacePatch" />
```

A PolygonPatch is a surface patch that is defined by a set of boundary curves and an underlying surface to which these curves adhere. The curves are coplanar and the polygon uses planar interpolation in its interior. Implements GM\_Polygon of ISO 19107.

The attribute "interpolation" specifies the interpolation mechanism used for this surface patch. Currently only planar surface patches are defined in GML 3, the attribute is fixed to "planar", i.e. the interpolation method shall return points on a single plane. The boundary of the patch shall be contained within that plane.

#### 10.2.2.6 gml:TriangleType, gml:Triangle

```
<complexType name="TriangleType">
  <complexContent>
    <extension base="gml:AbstractSurfacePatchType">
      <sequence>
        <element ref="gml:exterior" />
      </sequence>
      <attribute name="interpolation" type="gml:SurfaceInterpolationType" fixed="planar" />
    </extension>
  </complexContent>
</complexType>

<element name="Triangle" type="gml:TriangleType" substitutionGroup="gml:_SurfacePatch" />
```

Represents a triangle as a surface with an outer boundary consisting of a linear ring. Note that this is a polygon (subtype) with no inner boundaries. The number of points in the linear ring shall be four.

The Ring (element "exterior") shall be a LinearRing and shall form a triangle, the first and the last position shall be co-incident.

The attribute "interpolation" specifies the interpolation mechanism used for this surface patch. Currently only planar surface patches are defined in GML 3, the attribute is fixed to "planar", i.e. the interpolation method shall return points on a single plane. The boundary of the patch shall be contained within that plane.

#### 10.2.2.7 gml:RectangleType, gml:Rectangle

```
<complexType name="RectangleType">
  <complexContent>
    <extension base="gml:AbstractSurfacePatchType">
      <sequence>
        <element ref="gml:exterior" />
      </sequence>
      <attribute name="interpolation" type="gml:SurfaceInterpolationType" fixed="planar" />
    </extension>
  </complexContent>
</complexType>

<element name="Rectangle" type="gml:RectangleType" substitutionGroup="gml:_SurfacePatch" />
```

Represents a rectangle as a surface with an outer boundary consisting of a linear ring. Note that this is a polygon (subtype) with no inner boundaries. The number of points in the linear ring shall be five.

The Ring (element "exterior") shall be a LinearRing and shall form a rectangle; the first and the last position shall be co-incident.

The attribute "interpolation" specifies the interpolation mechanism used for this surface patch. Currently only planar surface patches are defined in GML 3, the attribute is fixed to "planar", i.e. the interpolation method shall return points on a single plane. The boundary of the patch shall be contained within that plane.

#### 10.2.2.8 gml:RingType

```
<complexType name="RingType">
  <complexContent>
    <extension base="gml:AbstractRingType">
      <sequence>
        <element ref="gml:curveMember" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

        </sequence>
      </extension>
    </complexContent>
  </complexType>

  <element name="Ring" type="gml:RingType" substitutionGroup="gml:_Ring" />

  <element name="curveMember" type="gml:CurvePropertyType" />

```

A Ring is used to represent a single connected component of a surface boundary. It consists of a sequence of curves connected in a cycle (an object whose boundary is empty).

A Ring is structurally similar to a composite curve in that the endPoint of each curve in the sequence is the startPoint of the next curve in the Sequence. Since the sequence is circular, there is no exception to this rule. Each ring, like all boundaries, is a cycle and each ring is simple.

NOTE Even though each Ring is simple, the boundary need not be simple. The easiest case of this is where one of the interior rings of a surface is tangent to its exterior ring.

The element “curveMember” references or contains one curve in the composite curve. The curves are contiguous, the collection of curves is ordered.

NOTE This definition allows for a nested structure, i.e. a CompositeCurve may use, for example, another CompositeCurve as a curve member.

This property element either references a curve via the XLink-attributes or contains the curve element. A curve element is any element which is substitutable for "gml:\_Curve".

The element is used, for example, in a Ring.

### 10.2.2.9 gml:RingPropertyType

```

<complexType name="RingPropertyType">
  <sequence>
    <element ref="gml:Ring" />
  </sequence>
</complexType>

```

Encapsulates a ring to represent properties in features or geometry collections.

### 10.2.2.10 gml:OrientableSurfaceType, gml:OrientableSurface, gml:baseSurface

```

<complexType name="OrientableSurfaceType">
  <complexContent>
    <extension base="gml:AbstractSurfaceType">
      <sequence>
        <element ref="gml:baseSurface" />
      </sequence>
      <attribute name="orientation" type="gml:SignType" default="+" />
    </extension>
  </complexContent>
</complexType>

<element name="baseSurface" type="gml:SurfacePropertyType" />

<element name="OrientableSurface" type="gml:OrientableSurfaceType" substitutionGroup="gml:_Surface" />

```

OrientableSurface consists of a surface and an orientation. If the orientation is "+", then the OrientableSurface is identical to the baseSurface. If the orientation is "-", then the OrientableSurface is a reference to a Surface with an up-normal that reverses the direction for this OrientableSurface, the sense of "the top of the surface".

The element “baseSurface” references or contains the base surface. The property “baseSurface” either references the base surface via the XLink-attributes or contains the surface element. A surface element is any element which is substitutable for “gml:\_Surface”. The base surface has positive orientation.

NOTE This definition allows for a nested structure, i.e. an OrientableSurface may use another OrientableSurface as its base surface.

If the attribute “orientation” is “+”, then the OrientableSurface is identical to the baseSurface. If the orientation is “-”, then the OrientableSurface is a reference to a Surface with an up-normal that reverses the direction for this OrientableSurface, the sense of “the top of the surface”. “+” is the default value.

### 10.2.2.11 gml:PointGrid

```
<group name="PointGrid">
  <sequence>
    <element name="row" maxOccurs="unbounded">
      <complexType>
        <sequence>
          <group ref="gml:geometricPositionListGroup"/>
        </sequence>
      </complexType>
    </element>
  </sequence>
</group>
```

Reference points which are organised into sequences or grids (sequences of equal length sequences).

### 10.2.2.12 gml:AbstractParametricCurveSurfaceType, gml:\_ParametricCurveSurface

```
<complexType name="AbstractParametricCurveSurfaceType">
  <complexContent>
    <extension base="gml:AbstractSurfacePatchType"/>
  </complexContent>
</complexType>

<element name="_ParametricCurveSurface" type="gml:AbstractParametricCurveSurfaceType" abstract="true"
substitutionGroup="gml:_SurfacePatch"/>
```

The surface patches that make up the parametric curve surface are all continuous families of curves, given by a constructive function of the form:

$$\text{surface}(s, t) : [a, b] \times [c, d] \rightarrow \text{DirectPosition}$$

By fixing, the value of either parameter, we have a one-parameter family of curves.

$$c_t(s) = c_s(t) = \text{surface}(s, t)$$

Various possible pairs of types of parametric curve surfaces:

Surface type	Horizontal curve type	Vertical curve type
GM_Cylinder	Circle, constant radii	Line Segment
GM_Cone	Circle, decreasing radii	Line Segment
GM_Sphere	Circle of constant latitude	Circle of constant longitude
GM_BilinearGrid	Line string	Line string
GM_BicubicGrid	Cubic spline	Cubic spline

The two partial derivatives of the surface parameterisation,  $i$  and  $j$  are given by:

$$i \equiv \frac{dsurface}{ds} = \frac{d}{ds} c_1(s) = \frac{\partial}{\partial s} surface(s,t)$$

.

and

$$j \equiv \frac{dsurface}{dt} = \frac{d}{dt} c_2(t) = \frac{\partial}{\partial t} surface(s,t)$$

The default upNormal for the surface shall be the vector cross product of these two curve derivatives when they are both non-zero.

$$k = i \times j$$

If the co-ordinate reference system is 2D, then the vector  $k$  extends the local co-ordinate system by supplying an "upward" elevation vector. In this case the vector basis  $(i,j)$  shall be a right hand system, that is to say, the oriented angle from  $i$  to  $j$  shall be less than 180 degrees. This gives a right-handed "moving frame" of local co-ordinate axes given by  $\langle i,j \rangle$ . A moving frame is defined to be a continuous function from the geometric object to a basis for the local tangent space of that object. For curves, this is the derivative of the curve, the local tangent. For surfaces, this is a local pair of tangents. Parameterised curve surfaces have a natural moving frame and it shall be used as defined in this paragraph to define the upNormal of the surface.

NOTE The existence of a viable moving frame is the definition of "orientable" manifold. This is why the existence of a continuous upNormal implies that the surface is orientable. Non-orientable surfaces, such as the Möbius band and Klein bottle are counter-intuitive. These are forbidden for use in application schemas conforming to this international standard. Klein bottles cannot even be constructed in 3D space, but require 4D space for non-singular representations.

### 10.2.2.13 gml:AbstractGriddedSurfaceType, gml:\_GriddedSurface

```
<complexType name="AbstractGriddedSurfaceType">
  <complexContent>
    <extension base="gml:AbstractParametricCurveSurfaceType">
      <sequence>
        <element name="rows" type="integer" minOccurs="0"/>
        <element name="columns" type="integer" minOccurs="0"/>
        <group ref="gml:PointGrid"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="_GriddedSurface" type="gml:AbstractGriddedSurfaceType" abstract="true"
substitutionGroup="gml:_ParametricCurveSurface"/>
```

A gridded surface is a parametric curve surface derived from a rectangular grid in the parameter space. The rows from this grid are control points for horizontal surface curves; the columns are control points for vertical surface curves. The working assumption is that for a pair of parametric co-ordinates (s, t) that the horizontal curves for each integer offset are calculated and evaluated at "s". This defines a sequence of control points:

```
<Cn(s) : s = 1 .. columns>
```

From this sequence a vertical curve is calculated for "s", and evaluated at "t". In most cases, the order of calculation (horizontal-vertical vs. vertical-horizontal) does not make a difference. Where it does, the horizontal- vertical order shall be the one used.

$$surface(s,t) = \sum_{i=0}^{row} \sum_{j=0}^{columns} w_i^2(s)w_j(t)\vec{P}_{i,j} \quad \text{where } \vec{P}_{i,j} \text{ is the control point in the } i^{\text{th}} \text{ row and } j^{\text{th}} \text{ column.}$$

Logically, any pair of curve interpolation types can lead to a subtype of GriddedSurface. The following clauses define some most commonly encountered surfaces that can be represented in this manner.

This is the double indexed sequence of control points, given in row major form.

NOTE There is no assumption made about the shape of the grid. For example, the positions need not effect a "2D/2D" surface, consecutive points may be equal in any or all of the ordinates. Further, the curves in either or both directions may close.

The attribute "rows" gives the number of rows in the parameter grid.

The attribute "columns" gives the number of columns in the parameter grid.

#### 10.2.2.14 gml:ConeType, gml:Cone

```
<complexType name="ConeType">
  <complexContent>
    <extension base="gml:AbstractGriddedSurfaceType">
      <attribute name="horizontalCurveType" type="gml:CurveInterpolationType"
        fixed="circularArc3Points"/>
      <attribute name="verticalCurveType" type="gml:CurveInterpolationType" fixed="linear"/>
    </extension>
  </complexContent>
</complexType>

<element name="Cone" type="gml:ConeType" substitutionGroup="gml:_GriddedSurface"/>
```

A cone is a gridded surface given as a family of conic sections whose control points vary linearly.

NOTE! A 5-point ellipse with all defining positions identical is a point. Thus, a truncated elliptical cone can be given as a 2x5 set of control points <<P1, P1, P1, P1, P1>, <P2, P3, P4, P5, P6>>. P1 is the apex of the cone. P2, P3, P4, P5 and P6 are any five distinct points around the base ellipse of the cone. If the horizontal curves are circles as opposed to ellipses, the circular cone can be constructed using <<P1, P1, P1>, <P2, P3, P4>>.

#### 10.2.2.15 gml:CylinderType, gml:Cylinder

```
<complexType name="CylinderType">
  <complexContent>
    <extension base="gml:AbstractGriddedSurfaceType">
      <attribute name="horizontalCurveType" type="gml:CurveInterpolationType"
        fixed="circularArc3Points"/>
    </extension>
  </complexContent>
</complexType>
```

```

        <attribute name="verticalCurveType" type="gml:CurveInterpolationType" fixed="linear"/>
      </extension>
    </complexContent>
  </complexType>

  <element name="Cylinder" type="gml:CylinderType" substitutionGroup="gml:_GriddedSurface"/>

```

A cylinder is a gridded surface given as a family of circles whose positions vary along a set of parallel lines, keeping the cross sectional horizontal curves of a constant shape.

NOTE! Given the same working assumptions as in the previous note, a Cylinder can be given by two circles, giving us the control points of the form <<P1, P2, P3>,<P4, P5, P6>>.

### 10.2.2.16 gml: SphereType, gml:Sphere

```

<complexType name="SphereType">
  <complexContent>
    <extension base="gml:AbstractGriddedSurfaceType">
      <attribute name="horizontalCurveType" type="gml:CurveInterpolationType"
        fixed="circularArc3Points"/>
      <attribute name="verticalCurveType" type="gml:CurveInterpolationType" fixed="circularArc3Points"/>
    </extension>
  </complexContent>
</complexType>

<element name="Sphere" type="gml:SphereType" substitutionGroup="gml:_GriddedSurface"/>

```

A sphere is a gridded surface given as a family of circles whose positions vary linearly along the axis of the sphere, and whose radius varies in proportions to the cosine function of the central angle. The horizontal circles resemble lines of constant latitude, and the vertical arcs resemble lines of constant longitude.

NOTE! If the control points are sorted in terms of increasing longitude, and increasing latitude, the upNormal of a sphere is the outward normal.

EXAMPLE If we take a gridded set of latitudes and longitudes in degrees,(u,v) such as

(-90, -180)	(-90, -90)	(-90,0)	(-90, 90)	(-90, 180)
(-45, -180)	(-45, -90)	(-45,0)	(-45, 90)	(-45, 180)
(0, -180)	(0, -90)	(0,0)	(0, 90)	(0, 180)
(45, -180)	(45, -90)	(45,0)	(45, -90)	(45, 180)
(90, -180)	(90, -90)	(90,0)	(90, -90)	(90, 180)

And map these points to 3D using the usual equations (where R is the radius of the required sphere).

$$z = R \sin u$$

$$x = (R \cos u)(\sin v)$$

$$y = (R \cos u)(\cos v)$$

We have a sphere of Radius R, centred at (0,0), as a gridded surface. Notice that the entire first row and the entire last row of the control points map to a single point in each 3D Euclidean space, North and South poles respectively, and that each horizontal curve closes back on itself forming a geometric cycle. This gives us a metrically bounded (of finite size), topologically unbounded (not having a boundary, a cycle) surface.

**10.2.2.17 gml:PolyhedralSurfaceType, gml:PolyhedralSurface**

```

<complexType name="PolyhedralSurfaceType">
  <complexContent>
    <restriction base="gml:SurfaceType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:polygonPatches"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>

<element name="PolyhedralSurface" type="gml:PolyhedralSurfaceType" substitutionGroup="gml:Surface"/>

```

A polyhedral surface is a surface composed of polygon surfaces connected along their common boundary curves. This differs from the surface type only in the restriction on the types of surface patches acceptable.

This property encapsulates the patches of the polyhedral surface.

**10.2.2.18 gml:PolygonPatchArrayPropertyType, gml:PolygonPatches**

```

<complexType name="PolygonPatchArrayPropertyType">
  <complexContent>
    <restriction base="gml:SurfacePatchArrayPropertyType">
      <sequence>
        <element ref="gml:PolygonPatch" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>

<element name="polygonPatches" type="gml:PolygonPatchArrayPropertyType" substitutionGroup="gml:patches"/>

```

This type defines a container for an array of polygon patches.

The property element contains a list of polygon patches. The order of the patches is significant and shall be preserved when processing the list.

**10.2.2.19 gml:TriangulatedSurfaceType, gml:TriangulatedSurface**

```

<complexType name="TrianglePatchArrayPropertyType">
  <complexContent>
    <restriction base="gml:SurfacePatchArrayPropertyType">
      <sequence>
        <element ref="gml:Triangle" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>

<element name="trianglePatches" type="TrianglePatchArrayPropertyType" substitutionGroup="gml:patches"/>

```

A triangulated surface is a polyhedral surface that is composed only of triangles. There is no restriction on how the triangulation is derived.

The triangle patches property encapsulates the patches of the triangulated surface.

### 10.2.2.20 gml:TrianglePatchArrayType, gml:TrianglePatches

```
<complexType name="TriangulatedSurfaceType">
  <complexContent>
    <restriction base="gml:SurfaceType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:trianglePatches"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>

<element name="TriangulatedSurface" type="gml:TriangulatedSurfaceType" substitutionGroup="gml:Surface"/>
```

This type defines a container for an array of triangle patches.

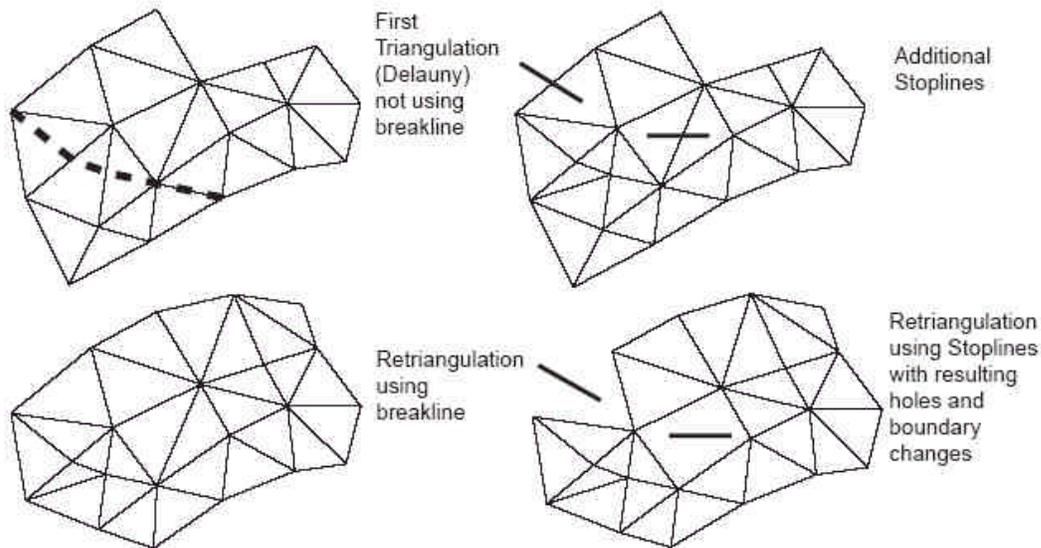

This property element contains a list of triangle patches. The order of the patches is significant and shall be preserved when processing the list.

### 10.2.2.21 gml:TinType, gml:Tin

```
<complexType name="TinType">
  <complexContent>
    <extension base="gml:TriangulatedSurfaceType">
      <sequence>
        <element name="stopLines" type="gml:LineStringSegmentArrayType"
          minOccurs="0" maxOccurs="unbounded"/>
        <element name="breakLines" type="gml:LineStringSegmentArrayType"
          minOccurs="0" maxOccurs="unbounded"/>
        <element name="maxLength" type="gml:LengthType"/>
        <element name="controlPoint">
          <complexType>
            <choice>
              <element ref="gml:posList"/>
              <group ref="gml:geometricPositionGroup"
                minOccurs="3" maxOccurs="unbounded"/>
            </choice>
          </complexType>
        </element>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Tin" type="gml:TinType" substitutionGroup="gml:TriangulatedSurface"/>
```

A tin is a triangulated surface that uses the Delauny algorithm or a similar algorithm complemented with consideration of breaklines, stoptines, and maximum length of triangle sides. These networks satisfy the Delauny's criterion away from the modifications: For each triangle in the network, the circle passing through its vertices does not contain, in its interior, the vertex of any other triangle.

Stoplines are lines where the local continuity or regularity of the surface is questionable. In the area of these pathologies, triangles intersecting a stopline shall be removed from the tin surface, leaving holes in the surface. If coincidence occurs on surface boundary triangles, the result shall be a change of the surface boundary. Stoplines contains all these pathological segments as a set of line strings.

Breaklines are lines of a critical nature to the shape of the surface, representing local ridges, or depressions (such as drainage lines) in the surface. As such their constituent segments shall be included in the tin even if doing so violates the Delauny criterion. Break lines contains these critical segments as a set of line strings.

Areas of the surface where data is not sufficiently dense to assure reasonable calculation shall be removed by adding a retention criterion for triangles based on the length of their sides. For many triangle sides exceeding maximum length, the adjacent triangles to that triangle side shall be removed from the surface.

The corners of the triangles in the TIN are often referred to as pots. ControlPoint shall contain a set of the positions used as posts for this TIN. Since each TIN contains triangles, there shall be at least 3 posts. The order in which these points are given does not affect the surface that is represented. Application schemas may add information based on ordering of control points to facilitate the reconstruction of the TIN from the control points.

#### 10.2.2.22 gml:LineStringSegmentArrayType

```
<complexType name="LineStringSegmentArrayType">
  <sequence>
    <element ref="gml:LineStringSegment" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

### 10.2.3 3-dimensional geometric primitives

#### 10.2.3.1 gml:AbstractSolidType, gml:\_Solid

```
<complexType name="AbstractSolidType">
  <complexContent>
    <extension base="gml:AbstractGeometricPrimitive" />
  </complexContent>
</complexType>
```

An abstraction of a solid to support the different levels of complexity. A solid is always contiguous.

```
<element name="_Solid" type="gml:AbstractSolidType" abstract="true"
substitutionGroup="gml:_GeometricPrimitive" />
```

The "\_Solid" element is the abstract head of the substitution group for all (continuous) solid elements.

### 10.2.3.2 gml:SolidPropertyType, gml:solidProperty

```
<complexType name="SolidPropertyType">
  <sequence>
    <element ref="gml:_Solid" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a solid as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="solidProperty" type="gml:SolidPropertyType" />
```

This property element either references a solid via the XLink-attributes or contains the solid element. solidProperty is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for \_Solid.

### 10.2.3.3 gml:SolidArrayPropertyType, gml:solidArrayProperty

```
<complexType name="SolidArrayPropertyType">
  <sequence>
    <element ref="gml:_Solid" minOccurs="0" maxOccurs="unbounded" />
  </sequence>
</complexType>
```

A container for an array of solids. The elements are always contained in the array property, referencing geometry elements or arrays of geometry elements is not supported.

```
<element name="solidArrayProperty" type="gml:SolidArrayPropertyType" />
```

This property element contains a list of solid elements. solidArrayProperty is the predefined property which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for a list of \_Solid.

### 10.2.3.4 gml:SolidType, gml:Solid

```
<complexType name="SolidType">
  <complexContent>
    <extension base="gml:AbstractSolidType">
      <sequence>
        <element name="exterior" type="gml:SurfacePropertyType" minOccurs="0" />
        <element name="interior" type="gml:SurfacePropertyType" minOccurs="0"
maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Solid" type="gml:SolidType" substitutionGroup="gml:_Solid" />
```

A solid is the basis for 3-dimensional geometry. The extent of a solid is defined by the boundary surfaces (shells). A shell is represented by a composite surface, where every shell is used to represent a single connected component of the boundary of a solid. It consists of a composite surface (a list of orientable surfaces) connected in a topological cycle (an object whose boundary is empty). Unlike a Ring, a shell's elements have no natural sort order. Like Rings, shells are simple.

The element "exterior" specifies the outer boundary of the solid. Boundaries of solids are similar to surface boundaries. In normal 3-dimensional Euclidean space, one (composite) surface is distinguished as the exterior. In the more general case, this is not always possible.

The element "interior" specifies the inner boundary of the solid. Boundaries of solids are similar to surface boundaries.

## 11 GML schemas – geometric complex, geometric composites and geometric aggregates

### 11.1 Overview

This clause describes the geometry model used by GML in the XML Schema documents:

- geometryAggregates.xsd
- geometryComplexes.xsd

The GML types and elements are described in the schemas listed in Annex C. The geometry schemas are identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:geometryAggregates:v3.1.0
urn:opengis:specification:gml:schema-xsd:geometryComplexes:v3.1.0
```

All types, elements and attributes in these XML Schema documents are covered by this Clause.

Geometric aggregates (i.e. instances of a subtype of AbstractGeometricAggregateType) are arbitrary aggregations of geometry elements. They are not assumed to have any additional internal structure and are used to "collect" pieces of geometry of a specified type. Application schemas may use aggregates for features that use multiple geometric objects in their representations.

Geometric complexes (i.e. instances of GeometricComplexType) are closed collections of geometric primitives, i.e. they will contain their boundaries. The composite geometries (CompositeCurve, CompositeSurface and CompositeSolid) can be viewed as primitives and as complexes. See Clause 7.6 and ISO 19107 for more details on the nature of composite geometries.

### 11.2 Geometric complex and geometric composites

A geometric complex is a set of primitive geometric objects (in a common coordinate system) whose interiors are disjoint. Further, if a primitive is in a geometric complex, then there exists a set of primitives in that complex whose point-wise union is the boundary of this first primitive.

A GeometricComplex in GML is a collection of geometrically disjoint, simple primitives. If a geometric primitive (other than a Point) is in a particular GeometricComplex, then there exists a set of primitives of lower dimension in the same complex that form the boundary of this primitive.

A geometric composite (GML specifies CompositeCurve, CompositeSurface or CompositeSolid) represents a geometric complex with an underlying core geometry that is isomorphic to a primitive. Thus, a composite curve is a collection of curves whose geometry could be viewed as a curve (albeit one with a complex inner

structure). Composites are intended for use as attribute values in datasets in which the underlying geometry has been decomposed, usually to expose its topological nature.

The members of a geometric composite shall represent a homogeneous collection of geometric primitives whose union would be the core geometry of the composite. The complex would include all member primitives *and* all primitives on the boundary of these primitives, and so forth until Points are included. Thus the „member“ properties in CompositeCurve, CompositeSurface and CompositeSolid represent a subset of the „element“ property of GeometricComplex.

Geometric complexes and composites shall be used in application schemas where the sharing of geometry is important.

For more information about geometric complexes and an extensive discussion about complexes/composites/primitives and their commonalities/differences see ISO 19107.

As XML Schema does not support the concept of “multiple inheritance” which is used in ISO 19107 to express the duality of the geometric composites (as an open primitive and as a closed complex) in the GML geometry model, the composites inherit from AbstractGeometricPrimitiveType only. However, by using a <choice> element, a composite can be used in any property, which expects a GeometricComplex as its value.

## 11.2.1 Composite Geometries

### 11.2.1.1 gml:CompositeCurveType, gml:CompositeCurve

```
<complexType name="CompositeCurveType">
  <complexContent>
    <extension base="gml:AbstractCurveType">
      <sequence>
        <element ref="gml:curveMember" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="CompositeCurve" type="gml:CompositeCurveType" substitutionGroup="gml:_Curve" />
```

A CompositeCurve is defined by a sequence of (orientable) curves such that the each curve in the sequence terminates at the start point of the subsequent curve in the list.

The element “curveMember” references or contains one curve in the composite curve.

The curves are contiguous, the collection of curves is ordered.

NOTE This definition allows for a nested structure, i.e. a CompositeCurve may use, for example, another CompositeCurve as a curve member.

### 11.2.1.2 gml:CompositeSurfaceType, gml:CompositeSurface

```
<complexType name="CompositeSurfaceType">
  <complexContent>
    <extension base="gml:AbstractSurfaceType">
      <sequence>
        <element ref="gml:surfaceMember" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="CompositeSurface" type="gml:CompositeSurfaceType" substitutionGroup="gml:_Surface" />
```

A CompositeSurface is defined by a set of orientable surfaces. A composite surface is geometry type with all the geometric properties of a (primitive) surface. Essentially, a composite surface is a collection of surfaces that join in pairs on common boundary curves and which, when considered as a whole, form a single surface.

The element “surfaceMember” references or contains one surface in the composite surface. The surfaces are contiguous.

NOTE This definition allows for a nested structure, i.e. a CompositeSurface may use, for example, another CompositeSurface as a member.

### 11.2.1.3 gml:CompositeSolidType, gml:CompositeSolid

```
<complexType name="CompositeSolidType">
  <complexContent>
    <extension base="gml:AbstractSolidType">
      <sequence>
        <element ref="gml:solidMember" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="CompositeSolid" type="gml:CompositeSolidType" substitutionGroup="gml:_Solid" />
```

A composite solid is a geometry type with all the geometric properties of a (primitive) solid.

Essentially, a composite solid is a collection of solids that join in pairs on common boundary surfaces and which, when considered as a whole, form a single solid.

The element “generator” references or contains one solid in the composite solid. The solids are contiguous.

NOTE This definition allows for a nested structure, i.e. a CompositeSolid may use, for example, another CompositeSolid as a member.

## 11.2.2 Geometric Complex

### 11.2.2.1 gml:GeometricComplexType, gml:GeometricComplex

```
<complexType name="GeometricComplexType">
  <complexContent>
    <extension base="gml:AbstractGeometryType">
      <sequence>
        <element name="element" type="gml:GeometricPrimitivePropertyType"
          maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="GeometricComplex" type="gml:GeometricComplexType" substitutionGroup="gml:_Geometry" />
```

A geometric complex. Every element “element” references or contains one geometric primitive (this includes composite geometries).

### 11.2.2.2 gml:GeometricComplexPropertyType

```
<complexType name="GeometricComplexPropertyType">
  <choice minOccurs="0">
    <element ref="gml:GeometricComplex" />
    <element ref="gml:CompositeCurve" />
    <element ref="gml:CompositeSurface" />
    <element ref="gml:CompositeSolid" />
  </choice>
```

```

    </choice>
    <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>

```

A property that has a geometric complex as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

NOTE The allowed geometry elements contained in such a property (or referenced by it) have to be modeled by an XML Schema choice element since the composites (conceptually) inherit both from geometric complex *and* geometric primitive and are already part of the `_GeometricPrimitive` substitution group.

## 11.3 Geometric Aggregates

### 11.3.1 Aggregates of unspecified dimensionality

#### 11.3.1.1 `gml:AbstractGeometricAggregateType`, `gml:_GeometricAggregate`

```

<complexType name="AbstractGeometricAggregateType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGeometryType" />
  </complexContent>
</complexType>

```

This is the abstract root type of the geometric aggregates.

```

<element name="_GeometricAggregate" type="gml:AbstractGeometricAggregateType" abstract="true"
substitutionGroup="gml:_Geometry" />

```

The `"_GeometricAggregate"` element is the abstract head of the substitution group for all geometric aggregates.

#### 11.3.1.2 `gml:MultiGeometryType`, `gml:MultiGeometry`, `gml:geometryMember`, `gml:geometryMembers`

```

<complexType name="MultiGeometryType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:geometryMember" minOccurs="0" maxOccurs="unbounded" />
        <element ref="gml:geometryMembers" minOccurs="0" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="MultiGeometry" type="gml:MultiGeometryType" substitutionGroup="gml:_GeometricAggregate" />

```

A geometry collection shall include one or more geometries, referenced through `geometryMember` elements.

The members of the geometric aggregate can be specified either using the "standard" property or the array property style. It is also valid to use both the "standard" and the array property style in the same collection.

NOTE Array properties cannot reference remote geometry elements via XLinks.

```

<element name="geometryMember" type="gml:GeometryPropertyType" />

```

This property element either references a geometry element via the XLink-attributes or contains the geometry element.

```

<element name="geometryMembers" type="gml:GeometryArrayPropertyType" />

```

This property element contains a list of geometry elements. The order of the elements is significant and shall be preserved when processing the array.

### 11.3.1.3 gml:MultiGeometryPropertyType, gml:multiGeometryProperty

```
<complexType name="MultiGeometryPropertyType">
  <sequence>
    <element ref="gml:_GeometricAggregate" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a geometric aggregate as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="multiGeometryProperty" type="gml:MultiGeometryPropertyType" />
```

This property element either references a geometric aggregate via the XLink-attributes or contains the "multi geometry" element. multiGeometryProperty is the predefined property, which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for \_GeometricAggregate.

## 11.3.2 0-dimensional aggregates

### 11.3.2.1 gml:MultiPointType, gml:MultiPoint, gml:pointMember, gml:pointMembers

```
<complexType name="MultiPointType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:pointMember" minOccurs="0" maxOccurs="unbounded" />
        <element ref="gml:pointMembers" minOccurs="0" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="MultiPoint" type="gml:MultiPointType" substitutionGroup="gml:_GeometricAggregate" />
```

A MultiPoint is defined by one or more Points, referenced through pointMember elements.

The members of the geometric aggregate can be specified either using the "standard" property or the array property style. It is also valid to use both the "standard" and the array property style in the same collection.

NOTE Array properties cannot reference remote geometry elements via XLinks.

```
<element name="pointMember" type="gml:PointPropertyType" />
```

This property element either references a Point via the XLink-attributes or contains the Point element.

```
<element name="pointMembers" type="gml:PointArrayPropertyType" />
```

This property element contains a list of points. The order of the elements is significant and shall be preserved when processing the array.

### 11.3.2.2 gml:MultiPointPropertyType, gml:multiPointProperty

```
<complexType name="MultiPointPropertyType">
  <sequence>
```

```

        <element ref="gml:MultiPoint" minOccurs="0"/>
    </sequence>
    <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>

```

A property that has a collection of points as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```

<element name="multiPointProperty" type="gml:MultiPointPropertyType" />

```

This property element either references a point aggregate via the XLink-attributes or contains the "multi point" element. multiPointProperty is the predefined property, which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for MultiPoint.

### 11.3.3 1-dimensional aggregates

#### 11.3.3.1 gml:MultiCurveType, gml:multiCurve, gml:curveMembers

```

<complexType name="MultiCurveType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:curveMember" minOccurs="0" maxOccurs="unbounded" />
        <element ref="gml:curveMembers" minOccurs="0" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="MultiCurve" type="gml:MultiCurveType" substitutionGroup="gml:_GeometricAggregate" />

```

A MultiCurve is defined by one or more Curves, referenced through curveMember elements.

The members of the geometric aggregate can be specified either using the "standard" property or the array property style. It is also valid to use both the "standard" and the array property style in the same collection.

NOTE Array properties cannot reference remote geometry elements via XLinks.

```

<element name="curveMembers" type="gml:CurveArrayPropertyType" />

```

This property element contains a list of curves. The order of the elements is significant and shall be preserved when processing the array.

#### 11.3.3.2 gml:MultiCurvePropertyType, gml:multiCurveProperty

```

<complexType name="MultiCurvePropertyType">
  <sequence>
    <element ref="gml:MultiCurve" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>

```

A property that has a collection of curves as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```

<element name="multiCurveProperty" type="gml:MultiCurvePropertyType" />

```

This property element either references a curve aggregate via the XLink-attributes or contains the "multi curve" element. multiCurveProperty is the predefined property, which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for MultiCurve.

### 11.3.3.3 gml:lineStringMember

```
<element name="lineStringMember" type="gml:LineStringPropertyType" />
```

Deprecated with GML 3.0 and included only for backwards compatibility with GML 2. Use "curveMember" instead.

This property element either references a line string via the XLink-attributes or contains the line string element.

### 11.3.3.4 gml:MultiLineStringType, gml:MultiLineString

```
<complexType name="MultiLineStringType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:lineStringMember" minOccurs="0" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A MultiLineString is defined by one or more LineStrings, referenced through lineStringMember elements. Deprecated with GML version 3.0. Use MultiCurveType instead.

```
<element name="MultiLineString" type="gml:MultiLineStringType" substitutionGroup="gml:_GeometricAggregate" />
```

Deprecated with GML 3.0 and included for backwards compatibility with GML 2. Use the "MultiCurve" element instead.

### 11.3.3.5 gml:MultiLineStringPropertyType

```
<complexType name="MultiLineStringPropertyType">
  <sequence>
    <element ref="gml:MultiLineString" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

This type is deprecated with GML 3.0 and shall not be used. It is included for backwards compatibility with GML 2. Use MultiCurvePropertyType instead.

A property that has a collection of line strings as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

## 11.3.4 2-dimensional aggregates

### 11.3.4.1 gml:MultiSurfaceType, gml:MultiSurface, gml:surfaceMember, gml:surfaceMembers

```
<complexType name="MultiSurfaceType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:surfaceMember" minOccurs="0" maxOccurs="unbounded" />
        <element ref="gml:surfaceMembers" minOccurs="0" />
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

        </sequence>
      </extension>
    </complexContent>
  </complexType>

```

```

<element name="MultiSurface" type="gml:MultiSurfaceType" substitutionGroup="gml:_GeometricAggregate" />

```

A MultiSurface is defined by one or more Surfaces, referenced through surfaceMember elements.

The members of the geometric aggregate can be specified either using the "standard" property or the array property style. It is also valid to use both the "standard" and the array property style in the same collection.

NOTE Array properties cannot reference remote geometry elements via XLinks.

```

<element name="surfaceMember" type="gml:SurfacePropertyType" />

```

This property element either references a surface via the XLink-attributes or contains the surface element. A surface element is any element, which is substitutable for "\_Surface".

```

<element name="surfaceMembers" type="gml:SurfaceArrayPropertyType" />

```

This property element contains a list of surfaces. The order of the elements is significant and shall be preserved when processing the array.

#### 11.3.4.2 gml:MultiSurfacePropertyType, gml:multiSurfaceProperty

```

<complexType name="MultiSurfacePropertyType">
  <sequence>
    <element ref="gml:MultiSurface" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>

```

A property that has a collection of surfaces as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```

<element name="multiSurfaceProperty" type="gml:MultiSurfacePropertyType" />

```

This property element either references a surface aggregate via the XLink-attributes or contains the "multi surface" element. multiSurfaceProperty is the predefined property, which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for MultiSurface.

#### 11.3.4.3 gml:MultiPolygonType, gml:MultiPolygon, gml:polygonMember

```

<complexType name="MultiPolygonType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:polygonMember" minOccurs="0" maxOccurs="unbounded" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A MultiPolygon is defined by one or more Polygons, referenced through polygonMember elements. *Deprecated with GML version 3.0. Use MultiSurfaceType instead.*

```

<element name="MultiPolygon" type="gml:MultiPolygonType" substitutionGroup="gml:_GeometricAggregate" />

```

Deprecated with GML 3.0 and included for backwards compatibility with GML 2. Use the "MultiSurface" element instead.

```
<element name="polygonMember" type="gml:PolygonPropertyType" />
```

Deprecated with GML 3.0 and included only for backwards compatibility with GML 2.0. Use "surfaceMember" instead.

This property element either references a polygon via the XLink-attributes or contains the polygon element.

#### 11.3.4.4 gml:MultiPolygonPropertyType

```
<complexType name="MultiPolygonPropertyType">
  <sequence>
    <element ref="gml:MultiPolygon" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

This type is deprecated with GML 3.0 and shall not be used. It is included for backwards compatibility with GML 2. Use MultiSurfacePropertyType instead.

A property that has a collection of polygons as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

### 11.3.5 3-dimensional aggregates

#### 11.3.5.1 gml:MultiSolidType, gml:MultiSolid, gml:solidMember, gml:solidMembers

```
<complexType name="MultiSolidType">
  <complexContent>
    <extension base="gml:AbstractGeometricAggregateType">
      <sequence>
        <element ref="gml:solidMember" minOccurs="0" maxOccurs="unbounded" />
        <element ref="gml:solidMembers" minOccurs="0" />
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="MultiSolid" type="gml:MultiSolidType" substitutionGroup="gml:_GeometricAggregate" />
```

A MultiSolid is defined by one or more Solids, referenced through solidMember elements.

The members of the geometric aggregate can be specified either using the "standard" property or the array property style. It is also valid to use both the "standard" and the array property style in the same collection.

NOTE Array properties cannot reference remote geometry elements via XLinks.

```
<element name="solidMember" type="gml:SolidPropertyType" />
```

This property element either references a solid via the XLink-attributes or contains the solid element. A solid element is any element, which is substitutable for "\_Solid".

```
<element name="solidMembers" type="gml:SolidArrayPropertyType" />
```

This property element contains a list of solids. The order of the elements is significant and shall be preserved when processing the array.

### 11.3.5.2 gml:MultiSolidPropertyType, gml:multiSolidProperty

```
<complexType name="MultiSolidPropertyType">
  <sequence>
    <element ref="gml:MultiSolid" minOccurs="0" />
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>
```

A property that has a collection of solids as its value domain can either be an appropriate geometry element encapsulated in an element of this type or an XLink reference to a remote geometry element (where remote includes geometry elements located elsewhere in the same document). Either the reference or the contained element shall be given, but neither both nor none.

```
<element name="multiSolidProperty" type="gml:MultiSolidPropertyType" />
```

This property element either references a solid aggregate via the XLink-attributes or contains the "multi solid" element. multiSolidProperty is the predefined property, which can be used by GML Application Schemas whenever a GML Feature has a property with a value that is substitutable for MultiSolid.

## 12 GML schemas – Coordinate reference systems schemas

### 12.1 Overview

#### 12.1.1 Introduction

This clause describes the six GML schema documents for encoding the definitions of coordinate reference systems and coordinate operations, explaining their contents, structure, and dependencies. Those six schema documents are:

- a) referenceSystems.xsd
- b) coordinateReferenceSystems.xsd
- c) datums.xsd
- d) coordinateSystems.xsd
- e) coordinateOperations.xsd
- f) dataQuality.xsd

All these schema documents are closely based on the UML package with a similar name in OGC Abstract Specification Topic 2, which is based on ISO 19111. All these schema documents are listed in Annex C. All these schema documents describe components in the <http://www.opengis.net/gml> namespace, for which the prefix **gml** is normally used.

#### 12.1.2 Coordinates

The position of a point can be described by (a set of) coordinates. Coordinates are unambiguous only when the associated coordinate reference system has been fully defined.

The geometry of spatial features might alternately be expressed in terms of invariant geometric quantities, viz. shapes and relative positions/orientations (strictly speaking only distance ratios and angles are invariant quantities). However, this would be unworkable: performing calculations on spatial data would become a major effort. The expression of the position of a point by coordinates introduces simplicity in terms of overview and calculus.

However, there is a price to be paid for this convenience. To describe a simple shape such as a triangle in a plane, six (plane) coordinates are required, whereas only a single distance ratio and an angle would suffice. The inherent degrees of freedom (four in 2D, seven in 3D) have to be satisfied by choosing the origin of the coordinate axes, their unit of measure, and the orientations of the axes. This choice underlines the fact that coordinates are human-defined quantities and not natural phenomena. Although this may seem self-evident, it is often overlooked and has consequences for the interpretation of coordinates and their error characteristics.

The choice of values for the parameters that constitute the degrees of freedom of the coordinate space is captured in the concept of a *coordinate reference system*. Without the full specification of the coordinate reference system, coordinates are ambiguous at best and meaningless at worst. The fact that such a choice *must* be made, either arbitrarily or by adopting values from survey measurements, leads to the large number of coordinate reference systems in use around the world. It also causes the little understood fact that the latitude and longitude of a point are not unique.

In this document, the term “coordinates” means the tuple of ordered scalar values that define the position of a single point in a coordinate reference system. The order of the values in the tuple and their unit(s) of measure are parts of the coordinate reference system definition. The tuple is composed of one, two, or three “ordinates”. The ordinates must be mutually independent and their number must be equal to the dimension of the coordinate space; for example, a tuple of coordinates may not contain two heights. In this document, the term “set of coordinates” is used to indicate the coordinates of multiple points.

However, it must be pointed out that usage in practice of the term “coordinates” is subject to ambiguity. Sometimes the term “coordinate” is used to indicate the tuple; the plural “coordinates” in that case describes the coordinates of multiple points. Others use the term “set of coordinates” to describe the coordinates of a single point. In that case the term “coordinate” is sometimes used instead of “ordinate”. The reader is advised to carefully infer the intended meaning from the context.

The concept of coordinates may be expanded from a strictly spatial context to include time. Time is then added as another ordinate to the coordinate tuple. It is even possible to add two time-coordinates, provided the two coordinates describe different independent quantities. An example of the latter is the time/space position of a subsurface point feature of which the vertical ordinate is expressed as the two-way travel time of a sound signal in milliseconds, as is common in seismic imaging and a second time ordinate indicates the time of observation, usually expressed in whole years.

In summary: each tuple of coordinates describing the position of a point shall be associated with a coordinate reference system. Instead of supplying the definition of the coordinate reference system with every single point, coordinates are often supplied in data sets in which all coordinates belong to the same coordinate reference system. Each data set then uses one coordinate reference system definition or reference, which applies to all coordinates in that data set.

### 12.1.3 Some geodetic concepts

Geodesy is the applied science that aims to determine the size and shape of the earth. In a more practical and local sense, this may be understood to mean the determination of the relative positions of points on or near the earth’s surface. Survey measurements and techniques are the means used to achieve this aim.

The most accurate reference shape approximating the earth is the geoid, the surface that is defined as the locus of all points with equal gravity at mean sea level. This shape excludes topography and the effects of tides, currents and weather on the oceans and seas. Topographic heights are typically expressed relative to the geoid. The gravity vector at mean sea level is everywhere perpendicular to this surface. Due to the irregular mass distribution in the earth’s interior, the geoid has an irregular shape. This makes the geoid unsuitable to use in calculations on spatial data; unfortunate because the familiar concept of height derives from the geoid and the geoid therefore implicitly plays an important role in all engineering and mapping activities. The direction of gravity also plays an important role in the mentioned survey techniques.

The geoid is approximated by the nearest regular body, an oblate spheroid, of which the oblateness corresponds to the flattening of the physical earth (and thus the geoid) at the poles due to the earth’s rotation. In survey practice, this spheroid is often referred to as an ellipsoid. Although mathematically the term “spheroid” is a more precise description than “ellipsoid”, the latter term is used in preference of “spheroid”, in

accordance with ISO 19111. The ellipsoid is a reasonably accurate approximation of the geoid, the latter undulating around the ellipsoid's surface with variations only in the order of several tens of metres.

The advantage of the ellipsoid is that it is much easier to work with mathematically than the geoid. The ellipsoid forms the basis of the best-known type of coordinate reference systems: the Geographic CRS. The position of a point relative to the ellipsoid is expressed by means of geographic coordinates: geodetic latitude ( $\varphi$ ) and geodetic longitude ( $\lambda$ ). The height ( $h$ ) above the ellipsoid is of not much practical use because everyday heights are related to the geoid (gravity-related heights, indicated by  $H$ ). Ellipsoidal height is an inseparable element of a 3D coordinate tuple, and originates either directly from a 3D survey technique (e.g. GPS) or from the transformation of horizontal coordinates extended with a gravity-related height.

Unfortunately there is not just one ellipsoid. An ellipsoid is a matter of choice, and therefore many choices are possible. The size and shape of the ellipsoid are traditionally chosen such that the surface of the geoid is matched as closely as possible locally, e.g. in a country, although a number global of best-fits are available. Each association of an ellipsoid with earth surface geometry results in the implicit choice of parameters to satisfy the degrees of freedom problem described in Subclause 12.1.2 above. In this case, the choice results in the definition of the origin, orientation, size, and shape of the ellipsoid. Collectively this choice is captured by the concept of "geodetic datum".

A Geographic CRS is not suitable for mapmaking on a planar surface, because it describes positions on a curved surface. It is impossible to represent such geometry in a Euclidean plane without introducing distortions. The need to control these distortions has given rise to the development of the science of map projections. Although some map projections can be represented as a geometric process, in general a map projection is a set of formulae that converts geodetic latitude and longitude to plane (map) coordinates. Height plays no role in this process, which is entirely two-dimensional.

Heights are traditionally determined separate from horizontal position in separate height networks, which is due to the different survey techniques used for the determination of horizontal and vertical geometry. Most practical heights are defined in close relationship with the gravity vector. Geodetic science distinguishes several different types of gravity-related heights. The differences between those are considered irrelevant for the purposes of this specification.

#### **12.1.4 Non-geodetic coordinate reference systems**

##### **12.1.4.1 Introduction**

In addition to the geographic and related coordinate reference systems discussed above, several other types of CRSs are when needed, and are handled by the GML schemas discussed. These other types of CRSs include:

##### **12.1.4.2 Geocentric CRS**

Type of coordinate reference system that deals with the earth's curvature by taking the 3D spatial view, which obviates the need to model the earth's curvature. The origin of a geocentric CRS is at the approximate centre of mass of the earth.

##### **12.1.4.3 Temporal CRS**

Used for the recording of time in association with any of the listed spatial coordinate reference systems.

##### **12.1.4.4 Engineering CRS**

Type of coordinate reference system that is used in a contextually local sense. This sub-type is used to model two broad categories of local coordinate reference systems:

- a) earth-fixed systems, applied to activities on or near the surface of the earth;

- b) spatial referencing by coordinates on moving platforms such as road vehicles, vessels, aircraft or spacecraft.

Earth-fixed Engineering CRSs are commonly based on a simple flat-earth approximation of the earth's surface, and the effect of earth curvature on feature geometry is ignored: calculations on coordinates use simple plane arithmetic without any corrections for earth curvature. The application of such Engineering CRSs to relatively small areas and "contextually local" is in this case equivalent to "spatially local".

One specialized type of earth-fixed Engineering CRS is a linear CRS, which represents position along a specified (usually not straight) line.

Engineering CRSs used on moving platforms are usually intermediate coordinate reference systems that are computationally required to calculate geodetic coordinates. These coordinate reference systems are subject to all the motions of the platform with which they are associated. In this case "contextually local" means that the associated coordinates are meaningful only relative to the moving platform. Earth curvature is usually irrelevant and is therefore ignored. In the spatial sense their applicability may extend from the immediate vicinity of the platform (e.g. a moving seismic ship) to the entire earth (e.g. in space applications). The determining factor is the mathematical model deployed in the positioning calculations. Transformation of coordinates from these moving Engineering CRSs to earth-referenced coordinate reference systems involves time-dependent coordinate operation parameters, which can be modelled by the structures provided in this UML model.

#### 12.1.4.5 Image CRS

An Image CRS is an Engineering CRS applied to images. Image CRSs warrant treatment as a separate sub-type because a separate user community exists for images with its own vocabulary. The definition of the associated Image Datum contains two data quantities not relevant for other datums and coordinate reference systems.

#### 12.1.4.6 Derived CRS

Some coordinate reference systems are defined by applying a coordinate conversion to another coordinate reference system. Such a coordinate reference system is called a Derived CRS, and the coordinate reference system it was derived from by applying the conversion is called the Source CRS. A coordinate conversion is an arithmetic operation with zero or more parameters that have defined values. The best-known example of a Derived CRS is a Projected CRS, which is always derived from a source Geographic CRS by applying the coordinate conversion known as a map projection.

An example of a Derived CRS of *derivedCRStype*: "geographic" is one of which the unit of measure has been modified with respect to an earlier defined Geographic CRS, which then takes the role of Source CRS. Another example is the CRS for a set of gridded data, where row and column coordinates reflect the position in the grid.

#### 12.1.5 Important XML elements

These XML Schemas encode definition data for both Coordinate Reference Systems (CRSs) and Coordinate Operations (including coordinate Transformations and Conversions). This definition data includes identification and specification data, both included as needed. The definition data for a CRS includes or references definition data for a Coordinate System and a Datum, as appropriate. When applicable, definition data for a CRS includes or references definition data for a Coordinate Operation, and vice-versa.

The specified XML encoding includes multiple alternative top level XML elements that can be used where needed. (That is, there is not a single top level element that may be the basis for all XML documents.) Most of these top level XML elements are GML objects that include identification information, allowing it to be referenced. The alternative top level XML elements include:

- a) All concrete XML elements in the substitution group headed by the abstract `CoordinateReferenceSystem` XML element. These elements can each be used to transfer the definition of one coordinate reference system of that type. These nine concrete XML elements are named:

- 1) CompoundCRS
  - 2) GeocentricCRS
  - 3) GeographicCRS
  - 4) ProjectedCRS
  - 5) EngineeringCRS
  - 6) ImageCRS
  - 7) VerticalCRS
  - 8) TemporalCRS
  - 9) DerivedCRS
- b) All concrete XML elements that are substitutable for the abstract CoordinateOperation XML element, namely:
- 1) ConcatenatedOperation. This element should be used to encode the definition of a concatenated coordinate conversion, which combines a specified sequence of Transformations and/or Conversions.
  - 2) PassThroughOperation. This element should be used to encode the definition of a pass through coordinate conversion, which uses a specified Conversion or Transformation to convert a subset of the coordinates of a CompoundCRS.
  - 3) Transformation. This element may be used to encode the definition of an approximate coordinate transformation, from one specified source coordinate reference system to another specified target coordinate reference system.
  - 4) Conversion. This element may be used to encode the definition of an exact coordinate conversion, from one coordinate reference system to another coordinate reference system.

NOTE 1 The Conversion and Transformation elements should not be used for well-known coordinate operation methods with many instances.

The concrete XML elements that are substitutable for CoordinateReferenceSystem use multiple lower level XML elements containing data structures. These lower level elements include all five concrete elements that are substitutable for the abstract Datum XML element, named:

- a) GeodeticDatum
- b) VerticalDatum
- c) TemporalDatum
- d) EngineeringDatum
- e) ImageDatum

These lower level XML elements also include all ten concrete elements that are substitutable for the abstract CoordinateSystem XML element, named:

- a) EllipsoidalCS

- b) VerticalCS
- c) CartesianCS
- d) ObliqueCartesianCS
- e) LinearCS
- f) PolarCS
- g) SphericalCS
- h) CylindricalCS
- i) TemporalCS
- j) UserDefinedCS

The concrete XML elements that are substitutable for the CoordinateOperation element use multiple lower level elements containing data structures, including the elements named:

- a) CovarianceMatrix
- b) CovarianceElement
- c) OperationMethod
- d) OperationParameter
- e) OperationParameterGroup
- f) ParameterValue
- g) ParameterValueGroup

NOTE 2 The ParameterValue and ParameterValueGroup elements should not be used for well-known coordinate operation methods with many instances.

## 12.2 referenceSystems schema

### 12.2.1 Overview

The reference systems schema, referenceSystems.xsd, has three logical parts, which define elements and types for XML encoding of the definitions of:

- a) Object identification, of the ten types of GML objects used for coordinate reference systems and coordinate operations
- b) Validity, of three types of GML objects
- c) High-level part of the definitions of coordinate reference systems

This schema encodes the Reference System package of the UML Model for OGC Abstract Specification Topic 2: Spatial Referencing by Coordinates. That UML model is adapted from ISO 19111 - Spatial referencing by coordinates, as described in Annex B of Topic 2. The SC\_CRS class is also encoded here, to eliminate the (circular) references from coordinateOperations.xsd to coordinateReferenceSystems.xsd. The RS\_SpatialReferenceSystemUsingGeographicIdentifier class is not encoded, since it is not applicable to coordinate positions. The CI\_Citation class is not directly encoded, since such information can be included as

metaDataProperty elements which are optionally allowed. A modified version of the EX\_Extent (DataType) class from ISO 19115 is currently encoded here, using GML 3 schema types.

The referenceSystems schema includes the dictionary.xsd, geometryBasic2d.xsd, and temporal.xsd GML schemas. This schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:referenceSystems:v3.1.0
```

## 12.2.2 Identification

### 12.2.2.1 gml:IdentifierType

```
<complexType name="IdentifierType">
  <sequence>
    <element ref="gml:name"/>
    <element ref="gml:version" minOccurs="0"/>
    <element ref="gml:remarks" minOccurs="0"/>
  </sequence>
</complexType>
```

An identification of a CRS object. The first use of the IdentifierType for an object, if any, is normally the primary identification code, and any others are aliases.

The IdentifierType uses gml:name for the Identifier code or name, often from a controlled list or pattern defined by a code space. The optional codeSpace attribute is normally included to identify or reference a code space within which one or more codes are defined. This code space is often defined by some authority organization, where one organization may define multiple code spaces. The range and format of each Code Space identifier is defined by that code space authority. Information about that code space authority can be included as metaDataProperty elements which are optionally allowed in all CRS objects.

### 12.2.2.2 gml:version

```
<element name="version" type="string"/>
```

Identifier of the version of the associated codeSpace or code, as specified by the codeSpace or code authority. This version is included only when the "code" or "codeSpace" uses versions. When appropriate, the version is identified by the effective date, coded using ISO 8601 date format.

### 12.2.2.3 gml:remarks

```
<element name="remarks" type="gml:StringOrRefType" substitutionGroup="gml:description"/>
```

Information about this code or alias. Contains text or refers to external text.

### 12.2.2.4 gml:SimpleNameType

```
<complexType name="SimpleNameType">
  <simpleContent>
    <restriction base="gml:CodeType">
      <attribute name="codeSpace" type="anyURI" use="prohibited"/>
    </restriction>
  </simpleContent>
</complexType>
```

The primary name of an object. The string in the CodeType contains the object identification name, and the codeSpace attribute is not included.

### 12.2.2.5 gml:scope

```
<element name="scope" type="string"/>
```

Description of the domain of usage, or limitations of usage, for which this CRS object is valid.

## 12.2.3 Validity

### 12.2.3.1 gml:validArea

```
<element name="validArea" type="gml:ExtentType"/>
```

Area or region in which this CRS object is valid

### 12.2.3.2 gml:ExtentType

```
<complexType name="ExtentType">
  <sequence>
    <element ref="gml:description" minOccurs="0"/>
    <choice>
      <element ref="gml:boundingBox" minOccurs="0" maxOccurs="unbounded"/>
      <element ref="gml:boundingPolygon" minOccurs="0" maxOccurs="unbounded"/>
    </choice>
    <element ref="gml:verticalExtent" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="gml:temporalExtent" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

Information about the spatial, vertical, and/or temporal extent of a reference system object. Constraints: At least one of the elements "description", "boundingBox", "boundingPolygon", "verticalExtent", and "temporalExtent" shall be included, but more than one can be included when appropriate. Furthermore, more than one "boundingBox", "boundingPolygon", "verticalExtent", and/or "temporalExtent" element can be included, with more than one meaning the union of the individual domains.

The "description" element contains a description of spatial and/or temporal extent of this object. The boundingBox and boundingPolygon are alternative elements for defining the Geographic domain of this reference system object. If the "srsName" value for the boundingBox element references a CRS that includes elevation and time, the verticalExtent and temporalExtent elements may not be needed.

The boundingBox elements are an unordered list of bounding boxes (or envelopes) whose union describes the spatial domain of this object. The boundingPolygon elements are an unordered list of bounding polygons whose union describes the spatial domain of this object. The verticalExtent elements are an unordered list of vertical intervals whose union describes the spatial domain of this object. The temporalExtent elements are an unordered list of time periods whose union describes the spatial domain of this object.

### 12.2.3.3 gml:boundingBox

```
<element name="boundingBox" type="gml:EnvelopeType"/>
```

A bounding box (or envelope) defining the spatial domain of this object.

### 12.2.3.4 gml:boundingPolygon

```
<element name="boundingPolygon" type="gml:PolygonType"/>
```

A bounding polygon horizontal defining the horizontal spatial domain of this object.

### 12.2.3.5 gml:verticalExtent

```
<element name="verticalExtent" type="gml:EnvelopeType"/>
```

An interval defining the vertical spatial domain of this object.

#### 12.2.3.6 gml:temporalExtent

```
<element name="temporalExtent" type="gml:TimePeriodType"/>
```

A time period defining the temporal domain of this object.

### 12.2.4 High-level coordinate reference system

#### 12.2.4.1 gml:\_ReferenceSystem

```
<element name="_ReferenceSystem" type="gml:AbstractReferenceSystemType" abstract="true"
substitutionGroup="gml:Definition"/>

<complexType name="AbstractReferenceSystemBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:srsName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>

<complexType name="AbstractReferenceSystemType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractReferenceSystemBaseType">
      <sequence>
        <element ref="gml:srsID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:validArea" minOccurs="0"/>
        <element ref="gml:scope" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

Description of a spatial and/or temporal reference system used by a dataset.

The AbstractReferenceSystemBaseType provides basic encoding for reference system objects, simplifying and restricting the DefinitionType as needed.

The "remarks" element contains comments on or information about this reference system, including source information.

The "srsID" elements contain a set of alternative identifications of this reference system. The first srsID, if any, is normally the primary identification code, and any others are aliases.

#### 12.2.4.2 gml:srsName

```
<element name="srsName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this reference system is identified.

#### 12.2.4.3 gml:srsID

```
<element name="srsID" type="gml:IdentifierType"/>
```

An identification of a reference system.

#### 12.2.4.4 gml:referenceSystemRef

```
<element name="referenceSystemRef" type="gml:ReferenceSystemRefType"
substitutionGroup="gml:dictionaryEntry"/>

<complexType name="ReferenceSystemRefType">
  <complexContent>
    <restriction base="gml:DictionaryEntryType">
      <sequence>
        <element ref="gml:_ReferenceSystem" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a reference system, either referencing or containing the definition of that reference system.

#### 12.2.4.5 gml:\_CRS

```
<element name="_CRS" type="gml:AbstractCRSType" abstract="true" substitutionGroup="gml:_ReferenceSystem"/>

<complexType name="AbstractCRSType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractReferenceSystemType"/>
  </complexContent>
</complexType>
```

Abstract coordinate reference system, usually defined by a coordinate system and a datum. This abstract complexType shall not be used, extended, or restricted, in an Application Schema, to define a concrete subtype with a meaning equivalent to a concrete subtype specified in this document.

#### 12.2.4.6 gml:crsRef

```
<element name="crsRef" type="gml:CRSRefType" substitutionGroup="gml:referenceSystemRef"/>

<complexType name="CRSRefType">
  <complexContent>
    <restriction base="gml:ReferenceSystemRefType">
      <sequence>
        <element ref="gml:_CRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a CRS abstract coordinate reference system, either referencing or containing the definition of that CRS.

### 12.3 coordinateReferenceSystems schema

#### 12.3.1 Overview

##### 12.3.1.1 Introduction

A coordinate reference system consists of a coordinate system that is (usually) related to the earth through one datum. A coordinate reference system may be single, compound, or derived.

The coordinate system is composed of a set of coordinate axes with specified units of measure. This concept implies the mathematical rules that define how coordinate values are calculated from distances, angles and other geometric elements and vice versa.

The datum defines the origin of the coordinate system and ties it to the earth, ensuring that the abstract mathematical concept “coordinate system” can be applied to the practical problem of describing positions of features on or near the earth’s surface by means of coordinates. The datum implicitly (occasionally explicitly) contains the values chosen for the set parameters that represent the degrees of freedom of the coordinate system, as described in Subclause 12.1.2 above. Each datum subtype can be associated with only specific types of coordinate systems.

### 12.3.1.2 Principal types of coordinate reference systems

Geodetic survey practice usually divides coordinate reference systems into a number of sub-types. The common classification criterion for sub-typing of coordinate reference systems can be described as the way in which they deal with earth curvature. This has a direct effect on the portion of the earth’s surface that can be covered by that type of CRS with an acceptable degree of error.

Thus the following principal sub-types of coordinate reference system are distinguished:

- a) **Geocentric.** Type of coordinate reference system that deals with the earth’s curvature by taking the 3D spatial view, which obviates the need to model the earth’s curvature. The origin of a geocentric CRS is at the approximate centre of mass of the earth.
- b) **Geographic.** Type of coordinate reference system based on an ellipsoidal approximation of the geoid. This provides an accurate representation of the geometry of geographic features for a large portion of the earth’s surface. Geographic coordinate reference systems can be 2D or 3D. A 2D Geographic CRS is used when positions of features are described on the surface of the reference ellipsoid; a 3D Geographic CRS is used when positions are described on, above or below the reference ellipsoid.
- c) **Projected.** Type of coordinate reference system that is based on an approximation of the shape of the earth’s surface by a plane. The distortion that is inherent in the approximation is carefully controlled and known. Distortion correction is commonly applied to calculated bearings and distances to produce values that are a close match to actual field values.
- d) **Engineering.** Type of coordinate reference system that is that is used only in a contextually local sense. This sub-type is used to model two broad categories of local coordinate reference systems:
  - earth-fixed systems, applied to engineering activities on or near the surface of the earth;
  - spatial referencing by coordinates on moving platforms such as road vehicles, vessels, aircraft or spacecraft.More information on Engineering CRSs is provided in Subclause 12.1.4.
- e) **Image.** An Image CRS is an Engineering CRS applied to images. Image CRSs warrant treatment are treated as a separate sub-type because a separate user community exists for images with its own vocabulary. The definition of the associated Image Datum contains two data attributes not relevant for other datums and coordinate reference systems.
- f) **Vertical.** Type of coordinate reference system used for the recording of heights or depths. Vertical CRSs make use of the direction of gravity to define the concept of height or depth, but its relationship with gravity may not be straightforward. By implication ellipsoidal heights ( $h$ ) cannot be captured in a vertical coordinate reference system. Ellipsoidal heights cannot exist independently, but only as inseparable part of a 3D coordinate tuple defined in a geographic 3D coordinate reference system.
- g) **Temporal.** Used for the recording of time in association with any of the listed spatial coordinate reference systems only.

EDITOR'S NOTE The CRS WG of the OGC has agreed to expand the types of CRS described above to also allow defining Earth Centered Inertial CRSs, which do not rotate with the Earth. However, the changes needed to do this have not yet been determined.

### 12.3.1.3 Compound coordinate reference systems

The traditional separation of horizontal and vertical position has resulted in different coordinate reference systems that are horizontal (2D) in nature and vertical (1D). Established practice combines the horizontal coordinates of a point with a height or depth from a different coordinate reference system to construct valid coordinates in 3D space. The coordinate reference system to which these 3D coordinates are referenced combines the separate horizontal and vertical coordinate reference systems of the horizontal and vertical coordinates. Such a coordinate system is called a compound coordinate reference system.

A Compound CRS is thus a coordinate reference system that combines an ordered sequence of two or more coordinate reference systems, none of which can themselves be compound. In general, a Compound CRS may contain any number of axes. The Compound CRS contains an ordered set of coordinate reference systems and the tuple order of a compound coordinate set shall follow that order, while the subsets of the tuple, described by each of the composing coordinate reference systems, shall follow the tuple order valid for their respective coordinate reference systems.

For spatial coordinates, a number of constraints exist for the construction of compound CRSs. For example, the coordinate reference systems that are combined should not contain any duplicate or redundant axes. Valid combinations include:

- a) Geographic 2D + Vertical
- b) Geographic 2D + Engineering 1D (near vertical)
- c) Projected + Vertical
- d) Projected + Engineering 1D (near vertical)
- e) Engineering (horizontal 2D or 1D linear) + Vertical

Any coordinate reference system or any of the above listed combinations of coordinate reference systems can have a temporal coordinate reference system added. More than one temporal coordinate reference system may be added if these axes represent different time quantities. For example, the oil industry sometimes uses "4D seismic", by which is meant seismic data with the vertical axis expressed in milliseconds (signal travel time). A second time axis indicates how it changes with time (years), e.g. as a reservoir is gradually exhausted of its recoverable oil or gas).

### 12.3.1.4 Derived coordinate reference systems

Some coordinate reference systems are defined by applying a coordinate conversion to another coordinate reference system. Such a coordinate reference system is called a Derived CRS, and the coordinate reference system it was derived from by applying the conversion is called the Source or Base CRS. A coordinate conversion is an arithmetic operation with zero or more parameters that have defined values. The Source CRS and Derived CRS have the same Datum. The best-known example of a Derived CRS is a Projected CRS, which is always derived from a source Geographic CRS by applying the coordinate conversion known as a map projection.

In principle, all sub-types of coordinate reference system may take on the role of either Source or Derived CRS with the exception of a Geocentric CRS and a Projected CRS. The latter is modelled as an object class under its own name, rather than as a general Derived CRS of type "projected". This has been done to honour common practice, which acknowledges Projected CRS's CRSs as one of the best known types of coordinate reference systems.

An example of a Derived CRS of *derivedCRStype*: "geographic" is one of which the unit of measure has been modified with respect to an earlier defined Geographic CRS, which then takes the role of Source CRS.

### 12.3.1.5 Schema introduction

The spatial-temporal coordinate reference systems schema, `coordinateReferenceSystems.xsd`, has two logical parts. One part defines elements and types for XML encoding of abstract coordinate reference systems definitions. The larger part defines specialized constructs for XML encoding of definitions of the multiple concrete types of spatial-temporal coordinate reference systems.

This schema encodes the Coordinate Reference System package of the UML Model for OGC Abstract Specification Topic 2: Spatial Referencing by Coordinates, with the exception of the abstract "SC\_CRS" class. That UML model is adapted from ISO 19111 - Spatial referencing by coordinates, as described in Annex B of Topic 2.

The `coordinateReferenceSystems` schema includes the `coordinateSystems.xsd`, `datums.xsd`, and `coordinateOperations.xsd` GML schemas. This schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:coordinateReferenceSystems:v3.1.0
```

### 12.3.2 Abstract coordinate reference systems

#### 12.3.2.1 gml:\_CoordinateReferenceSystem

```
<element name="_CoordinateReferenceSystem" type="gml:AbstractCoordinateReferenceSystemType"
  abstract="true" substitutionGroup="gml:_CRS"/>

<complexType name="AbstractCoordinateReferenceSystemType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractCRStype"/>
  </complexContent>
</complexType>
```

A coordinate reference system consists of an ordered sequence of coordinate system axes that are related to the earth through a datum. A coordinate reference system is defined by one datum and by one coordinate system. Most coordinate reference system do not move relative to the earth, except for engineering coordinate reference systems defined on moving platforms such as cars, ships, aircraft, and spacecraft. For further information, see Subclause 12.3.1.

Coordinate reference systems are commonly divided into sub-types. The common classification criterion for sub-typing of coordinate reference systems is the way in which they deal with earth curvature. This has a direct effect on the portion of the earth's surface that can be covered by that type of CRS with an acceptable degree of error. The exception to the rule is the subtype "Temporal" which has been added by analogy.

#### 12.3.2.2 gml:coordinateReferenceSystemRef

```
<element name="coordinateReferenceSystemRef" type="gml:CoordinateReferenceSystemRefType"
  substitutionGroup="gml:crsRef"/>

<complexType name="CoordinateReferenceSystemRefType">
  <complexContent>
    <restriction base="gml:CRSRefType">
      <sequence>
        <element ref="gml:_CoordinateReferenceSystem" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a coordinate reference system, either referencing or containing the definition of that reference system.

### 12.3.2.3 gml:\_GeneralDerivedCRS

```
<element name="_GeneralDerivedCRS" type="gml:AbstractGeneralDerivedCRSType" abstract="true"
substitutionGroup="gml:_CoordinateReferenceSystem"/>

<complexType name="AbstractGeneralDerivedCRSType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <element ref="gml:baseCRS"/>
        <element ref="gml:definedByConversion"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A coordinate reference system that is defined by its coordinate conversion from another coordinate reference system (not by a datum). This abstract complexType shall not be used, extended, or restricted, in an Application Schema, to define a concrete subtype with a meaning equivalent to a concrete subtype specified in this document.

### 12.3.2.4 gml:baseCRS

```
<element name="baseCRS" type="gml:CoordinateReferenceSystemRefType"/>
```

Association to the coordinate reference system used by this derived CRS.

### 12.3.2.5 gml:definedByConversion

```
<element name="definedByConversion" type="gml:GeneralConversionRefType"/>
```

Association to the coordinate conversion used to define this derived CRS.

### 12.3.2.6 gml:generalDerivedCRSRef

```
<element name="generalDerivedCRSRef" type="gml:GeneralDerivedCRSRefType"
substitutionGroup="gml:coordinateReferenceSystemRef"/>

<complexType name="GeneralDerivedCRSRefType">
  <complexContent>
    <restriction base="gml:CoordinateReferenceSystemRefType">
      <sequence>
        <element ref="gml:_GeneralDerivedCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a general derived coordinate reference system, either referencing or containing the definition of that reference system.

## 12.3.3 Concrete coordinate reference systems

### 12.3.3.1 gml:CompoundCRS

```
<element name="CompoundCRS" type="gml:CompoundCRSType" substitutionGroup="gml:_CRS"/>
```

```

<complexType name="CompoundCRSType">
  <complexContent>
    <extension base="gml:AbstractCRSType">
      <sequence>
        <element ref="gml:includesCRS" minOccurs="2" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A coordinate reference system describing the position of points through two or more independent coordinate reference systems.

The includesCRS elements are an ordered sequence of associations to all the component coordinate reference systems included in this compound coordinate reference system.

### 12.3.3.2 gml:includesCRS

```

<element name="includesCRS" type="gml:CoordinateReferenceSystemRefType"/>

```

An association to a component coordinate reference system included in this compound coordinate reference system.

### 12.3.3.3 gml:compoundCRSRef

```

<element name="compoundCRSRef" type="gml:CompoundCRSRefType" substitutionGroup="gml:crsRef"/>
<complexType name="CompoundCRSRefType">
  <complexContent>
    <restriction base="gml:CRSRefType">
      <sequence>
        <element ref="gml:CompoundCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a compound coordinate reference system, either referencing or containing the definition of that reference system.

### 12.3.3.4 gml:GeographicCRS

```

<element name="GeographicCRS" type="gml:GeographicCRSType"
  substitutionGroup="gml:_CoordinateReferenceSystem"/>
<complexType name="GeographicCRSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <element ref="gml:usesEllipsoidalICS"/>
        <element ref="gml:usesGeodeticDatum"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A coordinate reference system based on an ellipsoidal approximation of the geoid; this provides an accurate representation of the geometry of geographic features for a large portion of the earth's surface.

### 12.3.3.5 gml:usesEllipsoidalCS

```
<element name="usesEllipsoidalCS" type="gml:EllipsoidalCSRefType"/>
```

Association to the ellipsoidal coordinate system used by this CRS.

### 12.3.3.6 gml:usesGeodeticDatum

```
<element name="usesGeodeticDatum" type="gml:GeodeticDatumRefType"/>
```

Association to the geodetic datum used by this CRS

### 12.3.3.7 gml:geographicCRSRef

```
<element name="geographicCRSRef" type="gml:GeographicCRSRefType"
substitutionGroup="gml:coordinateReferenceSystemRef"/>
```

```
<complexType name="GeographicCRSRefType">
  <complexContent>
    <restriction base="gml:CoordinateReferenceSystemRefType">
      <sequence>
        <element ref="gml:GeographicCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a geographic coordinate reference system, either referencing or containing the definition of that reference system.

### 12.3.3.8 gml:VerticalCRS

```
<element name="VerticalCRS" type="gml:VerticalCRSType"
substitutionGroup="gml:_CoordinateReferenceSystem"/>
```

```
<complexType name="VerticalCRSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <element ref="gml:usesVerticalCS"/>
        <element ref="gml:usesVerticalDatum"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A 1D coordinate reference system used for recording heights or depths. Vertical CRSs make use of the direction of gravity to define the concept of height or depth, but the relationship with gravity may not be straightforward. By implication, ellipsoidal heights (h) cannot be captured in a vertical coordinate reference system. Ellipsoidal heights cannot exist independently, but only as an inseparable part of a 3D coordinate tuple defined in a geographic 3D coordinate reference system.

### 12.3.3.9 gml:usesVerticalCS

```
<element name="usesVerticalCS" type="gml:VerticalCSRefType"/>
```

Association to the vertical coordinate system used by this CRS.

### 12.3.3.10 gml:usesVerticalDatum

```
<element name="usesVerticalDatum" type="gml:VerticalDatumRefType"/>
```

Association to the vertical datum used by this CRS.

#### 12.3.3.11 gml:verticalCRSRef

```
<element name="verticalCRSRef" type="gml:VerticalCRSRefType"
  substitutionGroup="gml:coordinateReferenceSystemRef"/>

<complexType name="VerticalCRSRefType">
  <complexContent>
    <restriction base="gml:CoordinateReferenceSystemRefType">
      <sequence>
        <element ref="gml:VerticalCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a vertical coordinate reference system, either referencing or containing the definition of that reference system.

#### 12.3.3.12 gml:GeocentricCRS

```
<element name="GeocentricCRS" type="gml:GeocentricCRSType"
  substitutionGroup="gml:_CoordinateReferenceSystem"/>

<complexType name="GeocentricCRSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <choice>
          <element ref="gml:usesCartesianCS"/>
          <element ref="gml:usesSphericalCS"/>
        </choice>
        <element ref="gml:usesGeodeticDatum"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A 3D coordinate reference system with the origin at the approximate centre of mass of the earth. A geocentric CRS deals with the earth's curvature by taking a 3D spatial view, which obviates the need to model the earth's curvature.

#### 12.3.3.13 gml:usesCartesianCS

```
<element name="usesCartesianCS" type="gml:CartesianCSRefType"/>
```

Association to the Cartesian coordinate system used by this CRS.

#### 12.3.3.14 gml:usesSphericalCS

```
<element name="usesSphericalCS" type="gml:SphericalCSRefType"/>
```

Association to the spherical coordinate system used by this CRS.

#### 12.3.3.15 gml:geocentricCRSRef

```
<element name="geocentricCRSRef" type="gml:GeocentricCRSRefType"
  substitutionGroup="gml:coordinateReferenceSystemRef"/>
```

```

<complexType name="GeocentricCRSRefType">
  <complexContent>
    <restriction base="gml:CoordinateReferenceSystemRefType">
      <sequence>
        <element ref="gml:GeocentricCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a geocentric coordinate reference system, either referencing or containing the definition of that reference system.

### 12.3.3.16 gml:ProjectedCRS

```

<element name="ProjectedCRS" type="gml:ProjectedCRSType" substitutionGroup="gml:_GeneralDerivedCRS"/>
<complexType name="ProjectedCRSType">
  <complexContent>
    <extension base="gml:AbstractGeneralDerivedCRSType">
      <sequence>
        <element ref="gml:usesCartesianCS"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A 2D coordinate reference system used to approximate the shape of the earth on a planar surface, but in such a way that the distortion that is inherent to the approximation is carefully controlled and known. Distortion correction is commonly applied to calculated bearings and distances to produce values that are a close match to actual field values.

### 12.3.3.17 gml:projectedCRSRef

```

<element name="projectedCRSRef" type="gml:ProjectedCRSRefType"
  substitutionGroup="gml:generalDerivedCRSRef"/>
<complexType name="ProjectedCRSRefType">
  <complexContent>
    <restriction base="gml:GeneralDerivedCRSRefType">
      <sequence>
        <element ref="gml:ProjectedCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a projected coordinate reference system, either referencing or containing the definition of that reference system.

### 12.3.3.18 gml:DerivedCRS

```

<element name="DerivedCRS" type="gml:DerivedCRSType" substitutionGroup="gml:_GeneralDerivedCRS"/>
<complexType name="DerivedCRSType">
  <complexContent>
    <extension base="gml:AbstractGeneralDerivedCRSType">
      <sequence>
        <element ref="gml:derivedCRSType"/>
        <element ref="gml:usesCS"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

```

    </extension>
  </complexContent>
</complexType>

```

A coordinate reference system that is defined by its coordinate conversion from another coordinate reference system but is not a projected coordinate reference system. This category includes coordinate reference systems derived from a projected coordinate reference system.

#### 12.3.3.19 gml:derivedCRSType

```

<element name="derivedCRSType" type="gml:DerivedCRSTypeType"/>

<complexType name="DerivedCRSTypeType">
  <simpleContent>
    <restriction base="gml:CodeType">
      <attribute name="codeSpace" type="anyURI" use="required"/>
    </restriction>
  </simpleContent>
</complexType>

```

Type of a derived coordinate reference system. The required codeSpace attribute shall reference a source of information specifying the values and meanings of all the allowed string values for this DerivedCRSTypeType.

#### 12.3.3.20 gml:usesCS

```

<element name="usesCS" type="gml:CoordinateSystemRefType"/>

```

Association to the coordinate system used by this CRS.

#### 12.3.3.21 gml:derivedCRSRef

```

<element name="derivedCRSRef" type="gml:DerivedCRSRefType"
  substitutionGroup="gml:generalDerivedCRSRef"/>

<complexType name="DerivedCRSRefType">
  <complexContent>
    <restriction base="gml:GeneralDerivedCRSRefType">
      <sequence>
        <element ref="gml:DerivedCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a non-projected derived coordinate reference system, either referencing or containing the definition of that reference system.

#### 12.3.3.22 gml:EngineeringCRS

```

<element name="EngineeringCRS" type="gml:EngineeringCRSType"
  substitutionGroup="gml:_CoordinateReferenceSystem"/>

<complexType name="EngineeringCRSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <element ref="gml:usesCS"/>
        <element ref="gml:usesEngineeringDatum"/>
      </sequence>
    </extension>
  </complexContent>

```

```
</complexType>
```

A contextually local coordinate reference system; which can be divided into two broad categories:

- a) earth-fixed systems applied to engineering activities on or near the surface of the earth;
- b) CRSs on moving platforms such as road vehicles, vessels, aircraft, or spacecraft.

For further information, see Subclause 12.1.4.

#### 12.3.3.23 gml:usesEngineeringDatum

```
<element name="usesEngineeringDatum" type="gml:EngineeringDatumRefType"/>
```

Association to the engineering datum used by this CRS.

#### 12.3.3.24 gml:engineeringCRSRef

```
<element name="engineeringCRSRef" type="gml:EngineeringCRSRefType"
substitutionGroup="gml:coordinateReferenceSystemRef"/>
```

```
<complexType name="EngineeringCRSRefType">
  <complexContent>
    <restriction base="gml:CoordinateReferenceSystemRefType">
      <sequence>
        <element ref="gml:EngineeringCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to an engineering coordinate reference system, either referencing or containing the definition of that reference system.

#### 12.3.3.25 gml:ImageCRS

```
<element name=" " type="gml:ImageCRSType" substitutionGroup="gml:_CoordinateReferenceSystem"/>
```

```
<complexType name="ImageCRSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <choice>
          <element ref="gml:usesCartesianCS"/>
          <element ref="gml:usesObliqueCartesianCS"/>
        </choice>
        <element ref="gml:usesImageDatum"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

An engineering coordinate reference system applied to locations in images. Image coordinate reference systems are treated as a separate sub-type because a separate user community exists for images with its own terms of reference.

#### 12.3.3.26 gml:usesObliqueCartesianCS

```
<element name="usesObliqueCartesianCS" type="gml:ObliqueCartesianCSRefType"/>
```

Association to the oblique Cartesian coordinate system used by this CRS.

### 12.3.3.27 gml:usesImageDatum

```
<element name="usesImageDatum" type="gml:ImageDatumRefType"/>
```

Association to the image datum used by this CRS.

### 12.3.3.28 gml:imageCRSRef

```
<element name=" " type="gml:ImageCRSRefType" substitutionGroup="gml:coordinateReferenceSystemRef"/>

<complexType name="ImageCRSRefType">
  <complexContent>
    <restriction base="gml:CoordinateReferenceSystemRefType">
      <sequence>
        <element ref="gml:ImageCRS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to an image coordinate reference system, either referencing or containing the definition of that reference system.

### 12.3.3.29 gml:TemporalCRS

```
<element name="TemporalCRS" type="gml:TemporalCRSType"
substitutionGroup="gml:_CoordinateReferenceSystem"/>

<complexType name="TemporalCRSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateReferenceSystemType">
      <sequence>
        <element ref="gml:usesTemporalCS"/>
        <element ref="gml:usesTemporalDatum"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A 1D coordinate reference system used for the recording of time.

### 12.3.3.30 gml:usesTemporalCS

```
<element name="usesTemporalCS" type="gml:TemporalCSRefType"/>
```

Association to the temporal coordinate system used by this CRS.

### 12.3.3.31 gml:usesTemporalDatum

```
<element name="usesTemporalDatum" type="gml:TemporalDatumRefType"/>
```

Association to the temporal datum used by this CRS.

### 12.3.3.32 gml:temporalCRSRef

```
<element name="temporalCRSRef" type="gml:TemporalCRSRefType"
substitutionGroup="gml:coordinateReferenceSystemRef"/>

<complexType name="TemporalCRSRefType">
  <complexContent>
```

```

<restriction base="gml:CoordinateReferenceSystemRefType">
  <sequence>
    <element ref="gml:TemporalCRS" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</restriction>
</complexContent>
</complexType>

```

Association to a temporal coordinate reference system, either referencing or containing the definition of that reference system.

## 12.4 coordinateSystems schema

### 12.4.1 Overview

#### 12.4.1.1 Introduction

The coordinates of points are recorded in a coordinate system. A coordinate system is the set of coordinate system axes that spans the coordinate space. This concept implies the set of mathematical rules that determine how coordinates are associated with invariant quantities such as angles and distances. In other words, a coordinate system implies how coordinates are calculated from geometric elements such as distances and angles and vice versa. The calculus required to derive angles and distances from point coordinates and vice versa in a map plane is simple Euclidean 2D arithmetic. To do the same on the surface of an ellipsoid (curved 2D space) involves more complex ellipsoidal calculus. These rules cannot be specified in detail, but are implied in the geometric the properties of the coordinate space.

NOTE: The word ‘distances’ is used loosely in the above description. Strictly speaking distances are not invariant quantities, as they are expressed in the unit of measure defined for the coordinate system; ratios of distances are invariant.

One coordinate system may be used by multiple coordinate reference systems. A coordinate system is composed of an ordered sequence of axes, the number of axes being equal to the dimension of the space of which it describes the geometry. Coordinates in coordinate tuples shall be listed in the specified axes sequence and units.

The dimension of the coordinate space, the names, the units of measure, the directions and sequence of the axes are all part of the Coordinate System definition. The number of coordinates in a tuple and the number of axes in a coordinate system shall be equal.

Example: It is therefore not permitted to supply a coordinate tuple with two heights of different definition in the same coordinate tuple.

#### 12.4.1.2 Coordinate system types

Coordinate systems are divided in types by the geometric properties of the coordinate space spanned and the geometric properties of the axes themselves (straight or curved; perpendicular or not). Certain types of coordinate system can only be used with specific subtypes of coordinate reference system. A description of coordinate system types is provided in Table TBD.

**Table 3 — Types of coordinate systems with CRS constraints**

CS type	Description	Used by CRS type
Cartesian	1-, 2-, or 3-dimensional coordinate system that gives the position of points relative to 2 or 3 orthogonal straight axes in the 2- or 3-dimensional case. In the 1-dimensional case, it contains a single straight coordinate axis. In the multi-dimensional case all axes shall have the same unit of measure.	Geocentric Projected Engineering Image Derived

oblique Cartesian	2- or 3-dimensional coordinate system with straight axes that are not necessarily orthogonal	Engineering Image Derived
ellipsoidal	2- or 3-dimensional coordinate system in which position is specified by geodetic latitude, geodetic longitude and (in the three-dimensional case) ellipsoidal height, associated with one or more geographic coordinate reference systems.	Geographic Engineering Derived
vertical	1-dimensional coordinate system used to record the heights (or depths) of points dependent on the Earth's gravity field. An exact definition is deliberately not provided as the complexities of the subject fall outside the scope of this specification.	Vertical Engineering Derived
linear	1-dimensional coordinate system that consists of the points which lie on the single axis described. The associated ordinate is the distance from the specified origin to the point along the axis. Example: usage of the line feature representing a road to describe points on or along that road.	Engineering Derived
user-defined	2- or 3-dimensional coordinate system that consists of any combination of coordinate axes not covered by any other coordinate system type. An example is a multilinear coordinate system which contains one coordinate axis that may have any 1-D shape which has no intersections with itself. This non-straight axis is supplemented by one or two straight axes to complete a 2 or 3 dimensional coordinate system.	Engineering Derived
temporal	1-dimensional coordinate system containing a single time axis and used to describe the temporal position of a point in the specified time units from a specified time origin.	Temporal
spherical	3-dimensional coordinate system with one distance, measured from the origin, and two angular coordinates; not to be confused with an ellipsoidal coordinate system based on an ellipsoid 'degenerated' into a sphere	Geocentric Engineering Derived
cylindrical	3-dimensional coordinate system consisting of a polar coordinate system extended by a straight coordinate axis perpendicular to the plane spanned by the polar coordinate system.	Engineering Derived
polar	2-dimensional coordinate system in which position is specified by the distance from the origin and the angle between the line from origin to point and a reference direction.	Engineering Derived

### 12.4.1.3 Coordinate system axis

A coordinate system is composed of an ordered set of coordinate system axes. Each of its axes is completely characterised by a unique combination of axis name, axis abbreviation, axis direction and axis unit of measure.

The concept of coordinate axis requires some clarification. Consider an arbitrary  $x, y, z$  coordinate system. The  $x$ -axis may be defined as the locus of points with  $y = z = 0$ . This is easily enough understood if the  $x, y, z$  coordinate system is a Cartesian system and the space it describes is Euclidean. It becomes a bit more difficult to understand in the case of a strongly curved space, such as the surface of an ellipsoid, its geometry described by an ellipsoidal coordinate system (2D or 3D). Applying the same definition by analogy to the curvilinear *latitude* and *longitude* coordinates, the latitude axis would be the equator and the longitude axis would be the prime meridian, which is not a satisfactory definition.

Bearing in mind that the order of the coordinates in a coordinate tuple shall be the same as the defined order of the coordinate axes, the ' $i$ -th' coordinate axis of a coordinate system is defined as the locus of points for which all coordinates with sequence number not equal to ' $i$ ', have a constant value locally (whereby  $i = 1 \dots n$ , and  $n$  is the dimension of the coordinate space).

It will be evident that the addition of the word 'locally' in this definition apparently adds an element of ambiguity and this is intentional. However, the definition of the coordinate parameter associated with any axis shall be unique. The coordinate axis itself should not be interpreted as a unique mathematical object, the associated coordinate parameter should.

Example 1 Geodetic latitude is defined as the “Angle from the equatorial plane to the perpendicular to the ellipsoid through a given point, northwards usually treated as positive”. However, when used in an ellipsoidal coordinate system, the geodetic latitude axis will be described as pointing ‘north’. In two different points on the ellipsoid the direction ‘north’ will be a spatially different direction, but the concept of latitude is the same.

Furthermore the specified directions of the coordinate axes are often only approximate; two geographic coordinate reference systems will make use of the same ellipsoidal coordinate system. These coordinate systems are associated with the earth through two different geodetic datums, which may lead to the two systems being slightly rotated w.r.t. each other.

Usage of coordinate system axis names is constrained by geodetic custom in a number of cases, depending mainly on the coordinate reference system type. These constraints are shown in Table TBD. These constraints work in two directions; for example the names ‘geodetic latitude’ and ‘geodetic longitude’ shall be used to designate the coordinate axis names associated with a geographic coordinate reference system. Conversely, these names shall not be used in any other context. Image and engineering coordinate reference systems may make use of names specific to the local context or custom and are therefore not included as constraints in this list.

**Table 4 — Naming constraints for coordinate system axes**

CS	CRS	Permitted coordinate system axis names
Cartesian	Geocentric	Geocentric X, Geocentric Y, Geocentric Z
Spherical	Geocentric	Spherical Latitude, Spherical Longitude, Geocentric Radius
Ellipsoidal	Geographic	Geodetic latitude, Geodetic longitude, Ellipsoidal height (if 3D)
Vertical	Vertical	Gravity-related height
Vertical	Vertical	Depth
Cartesian	Projected	Easting, Northing
Cartesian	Projected	Westing, Southing

Example 2 The combination {Latitude, Lat, north, degree} would lead to one instance of the object class ‘coordinate system axis’; the combination {Latitude,  $\phi$ , north, degree} to another instance, the axis abbreviation being different.

#### 12.4.1.4 Schema introduction

The coordinate systems schema, coordinateSystems.xsd, has three logical parts, which define elements and types for XML encoding of the definitions of:

- a) Coordinate system axes
- b) Abstract coordinate system
- c) Multiple concrete types of spatial-temporal coordinate systems

This schema encodes the Coordinate System package of the UML Model for OGC Abstract Specification Topic 2: Spatial Referencing by Coordinates. That UML model is adapted from ISO 19111 - Spatial referencing by coordinates, as described in Annex B of Topic 2.

The referenceSystems schema includes the referenceSystems.xsd GML schema. This schema is identified by the following location-independent name (using URN syntax):

urn:opengis:specification:gml:schema-xsd:coordinateSystems:v3.1.0

## 12.4.2 Coordinate system axes

### 12.4.2.1 gml:CoordinateSystemAxis

```
<element name="CoordinateSystemAxis" type="gml:CoordinateSystemAxisType"
  substitutionGroup="gml:Definition"/>

<complexType name="CoordinateSystemAxisType">
  <complexContent>
    <extension base="gml:CoordinateSystemAxisBaseType">
      <sequence>
        <element ref="gml:axisID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:axisAbbrev"/>
        <element ref="gml:axisDirection"/>
      </sequence>
      <attribute ref="gml:uom" use="required"/>
    </extension>
  </complexContent>
</complexType>

<complexType name="CoordinateSystemAxisBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:axisName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

Definition of a coordinate system axis.

The `CoordinateSystemAxisBaseType` provides the basic encoding for coordinate system axis objects, simplifying and restricting the `DefinitionType` as needed.

The "axisID" elements contain a set of alternative identifications of this coordinate system axis. The first axisID, if any, is normally the primary identification code, and any others are aliases.

The "remarks" element contains comments on or information about this reference system, including source information.

### 12.4.2.2 gml:axisName

```
<element name="axisName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this coordinate system axis is identified.

### 12.4.2.3 gml:axisID

```
<element name="axisID" type="gml:IdentifierType"/>
```

An identification of a coordinate system axis.

### 12.4.2.4 gml:axisAbbrev

```
<element name="axisAbbrev" type="gml:CodeType"/>
```

The abbreviation used for this coordinate system axis. This abbreviation can be used to identify the ordinates in a coordinate tuple. Examples are X and Y. The codeSpace attribute can reference a source of more information on a set of standardized abbreviations, or on this abbreviation.

#### 12.4.2.5 gml:axisDirection

```
<element name="axisDirection" type="gml:CodeType"/>
```

Direction of this coordinate system axis (or in the case of Cartesian projected coordinates, the direction of this coordinate system axis at the origin). Examples: north or south, east or west, up or down. Within any set of coordinate system axes, only one of each pair of terms can be used. For earth-fixed CRSs, this direction is often approximate and intended to provide a human interpretable meaning to the axis. When a geodetic datum is used, the precise directions of the axes may therefore vary slightly from this approximate direction. Note that an EngineeringCRS can include specific descriptions of the directions of its coordinate system axes. For example, the path of a linear CRS axis can be referenced in another document, such as referencing a GML feature that references or includes a curve geometry. The codeSpace attribute can reference a source of more information on a set of standardized directions, or on this direction.

#### 12.4.2.6 gml:uom

```
<attribute name="uom" type="anyURI"/>
```

Identifier of the unit of measure used for this coordinate system axis. The value of this coordinate in a coordinate tuple shall be recorded using this unit of measure, whenever those coordinates use a coordinate reference system that uses a coordinate system that uses this axis.

#### 12.4.2.7 gml:coordinateSystemAxisRef

```
<element name="coordinateSystemAxisRef" type="gml:CoordinateSystemAxisRefType"
substitutionGroup="gml:dictionaryEntry"/>
```

```
<complexType name="CoordinateSystemAxisRefType">
  <complexContent>
    <restriction base="gml:DictionaryEntryType">
      <sequence>
        <element ref="gml:CoordinateSystemAxis" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a coordinate system axis, either referencing or containing the definition of that axis.

### 12.4.3 Abstract coordinate system

#### 12.4.3.1 gml:\_CoordinateSystem

```
<element name="_CoordinateSystem" type="gml:AbstractCoordinateSystemType" abstract="true"
substitutionGroup="gml:Definition"/>
```

```
<complexType name="AbstractCoordinateSystemType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemBaseType">
      <sequence>
        <element ref="gml:csID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:usesAxis" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

<complexType name="AbstractCoordinateSystemBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:csName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>

```

A coordinate system (CS) is the set of coordinate system axes that spans a given coordinate space. A CS is derived from a set of (mathematical) rules for specifying how coordinates in a given space are to be assigned to points. This abstract complexType shall not be used, extended, or restricted, in an Application Schema, to define a concrete subtype with a meaning equivalent to a concrete subtype specified in this document.

The AbstractCoordinateSystemBaseType provides the basic encoding for coordinate system objects, simplifying and restricting the DefinitionType as needed.

The "csID" elements contain a set of alternative identifications of this coordinate system. The first csID, if any, is normally the primary identification code, and any others are aliases.

The usesAxis elements are an ordered sequence of associations to the coordinate system axes included in this coordinate system. The coordinate values in a coordinate tuple shall be recorded in the order in which the coordinate system axes associations are recorded, whenever those coordinates use a coordinate reference system that uses this coordinate system.

The "remarks" element contains comments on or information about this reference system, including source information.

#### 12.4.3.2 gml:csName

```

<element name="csName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>

```

The name by which this coordinate system is identified.

#### 12.4.3.3 gml:csID

```

<element name="csID" type="gml:IdentifierType"/>

```

An identification of a coordinate system.

#### 12.4.3.4 gml:usesAxis

```

<element name="usesAxis" type="gml:CoordinateSystemAxisRefType" substitutionGroup="gml:dictionaryEntry"/>

```

#### 12.4.3.5 Association to a coordinate system axis.gml:coordinateSystemRef

```

<element name="coordinateSystemRef" type="gml:CoordinateSystemRefType"/>

```

```

<complexType name="CoordinateSystemRefType">
  <complexContent>
    <restriction base="gml:DictionaryEntryType">
      <sequence>
        <element ref="gml:_CoordinateSystem" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

```

    </restriction>
  </complexContent>
</complexType>

```

Association to a coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4 Concrete coordinate systems

##### 12.4.4.1 gml:EllipsoidalCS

```

<element name="EllipsoidalCS" type="gml:EllipsoidalCSType" substitutionGroup="gml:_CoordinateSystem"/>

<complexType name="EllipsoidalCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>

```

A two- or three-dimensional coordinate system in which position is specified by geodetic latitude, geodetic longitude, and (in the three-dimensional case) ellipsoidal height. An EllipsoidalCS shall have two or three usesAxis associations.

##### 12.4.4.2 gml:ellipsoidalCSRef

```

<element name="ellipsoidalCSRef" type="gml:EllipsoidalCSRefType"
  substitutionGroup="gml:coordinateSystemRef"/>

<complexType name="EllipsoidalCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:EllipsoidalCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to an ellipsoidal coordinate system, either referencing or containing the definition of that coordinate system.

##### 12.4.4.3 gml:CartesianCS

```

<element name="CartesianCS" type="gml:CartesianCSType" substitutionGroup="gml:_CoordinateSystem"/>

<complexType name="CartesianCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>

```

A 1-, 2-, or 3-dimensional coordinate system. Gives the position of points relative to orthogonal straight axes in the 2- and 3-dimensional cases. In the 1-dimensional case, it contains a single straight coordinate axis. In the multi-dimensional case, all axes shall have the same length unit of measure. A CartesianCS shall have one, two, or three usesAxis associations.

##### 12.4.4.4 gml:cartesianCSRef

```

<element name="cartesianCSRef" type="gml:CartesianCSRefType" substitutionGroup="gml:coordinateSystemRef"/>

<complexType name="CartesianCSRefType">
  <complexContent>

```

```

    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:CartesianCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a Cartesian coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.5 gml:VerticalCS

```

<element name="VerticalCS" type="gml:VerticalCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="VerticalCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>

```

A one-dimensional coordinate system used to record the heights (or depths) of points. Such a coordinate system is usually dependent on the Earth's gravity field, perhaps loosely as when atmospheric pressure is the basis for the vertical coordinate system axis. A VerticalCS shall have one usesAxis association.

#### 12.4.4.6 gml:verticalCSRef

```

<element name="verticalCSRef" type="gml:VerticalCSRefType" substitutionGroup="gml:coordinateSystemRef"/>
<complexType name="VerticalCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:VerticalCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a vertical coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.7 gml:TemporalCS

```

<element name="TemporalCS" type="gml:TemporalCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="TemporalCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>

```

A one-dimensional coordinate system containing a single time axis, used to describe the temporal position of a point in the specified time units from a specified time origin. A TemporalCS shall have one usesAxis association.

#### 12.4.4.8 gml:temporalCSRef

```

<element name="temporalCSRef" type="gml:TemporalCSRefType" substitutionGroup="gml:coordinateSystemRef"/>

```

```

<complexType name="TemporalCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:TemporalCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a temporal coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.9 gml:LinearCS

```

<element name="LinearCS" type="gml:LinearCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="LinearCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>

```

A one-dimensional coordinate system that consists of the points that lie on the single axis described. The associated ordinate is the distance from the specified origin to the point along the axis. Example: usage of the line feature representing a road to describe points on or along that road. A LinearCS shall have one usesAxis association.

#### 12.4.4.10 gml:linearCSRef

```

<element name="linearCSRef" type="gml:LinearCSRefType" substitutionGroup="gml:coordinateSystemRef"/>
<complexType name="LinearCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:LinearCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a linear coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.11 gml:UserDefinedCS

```

<element name="UserDefinedCS" type="gml:UserDefinedCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="UserDefinedCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>

```

A two- or three-dimensional coordinate system that consists of any combination of coordinate axes not covered by any other coordinate system type. An example is a multilinear coordinate system which contains one coordinate axis that may have any 1-D shape which has no intersections with itself. This non-straight axis is supplemented by one or two straight axes to complete a 2 or 3 dimensional coordinate system. The non-straight axis is typically incrementally straight or curved. A UserDefinedCS shall have two or three usesAxis associations.

#### 12.4.4.12 gml:userDefinedCSRef

```
<element name="userDefinedCSRef" type="gml:UserDefinedCSRefType"
  substitutionGroup="gml:coordinateSystemRef"/>
<complexType name="UserDefinedCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:UserDefinedCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a user-defined coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.13 gml:SphericalCS

```
<element name="SphericalCS" type="gml:SphericalCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="SphericalCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>
```

A three-dimensional coordinate system with one distance measured from the origin and two angular coordinates. Not to be confused with an ellipsoidal coordinate system based on an ellipsoid "degenerated" into a sphere. A SphericalCS shall have three usesAxis associations.

#### 12.4.4.14 gml:sphericalCSRef

```
<element name="sphericalCSRef" type="gml:SphericalCSRefType" substitutionGroup="gml:coordinateSystemRef"/>
<complexType name="SphericalCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:SphericalCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a spherical coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.15 gml:PolarCS

```
<element name="PolarCS" type="gml:PolarCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="PolarCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>
```

A two-dimensional coordinate system in which position is specified by the distance from the origin and the angle between the line from the origin to a point and a reference direction. A PolarCS shall have two usesAxis associations.

#### 12.4.4.16 gml:polarCSRef

```
<element name="polarCSRef" type="gml:PolarCSRefType" substitutionGroup="gml:coordinateSystemRef"/>
<complexType name="PolarCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:PolarCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a polar coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.17 gml:CylindricalCS

```
<element name="CylindricalCS" type="gml:CylindricalCSType" substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="CylindricalCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>
```

A three-dimensional coordinate system consisting of a polar coordinate system extended by a straight coordinate axis perpendicular to the plane spanned by the polar coordinate system. A CylindricalCS shall have three usesAxis associations.

#### 12.4.4.18 gml:cylindricalCSRef

```
<element name="cylindricalCSRef" type="gml:CylindricalCSRefType"
substitutionGroup="gml:coordinateSystemRef"/>
<complexType name="CylindricalCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:CylindricalCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a cylindrical coordinate system, either referencing or containing the definition of that coordinate system.

#### 12.4.4.19 gml:ObliqueCartesianCS

```
<element name="ObliqueCartesianCS" type="gml:ObliqueCartesianCSType"
substitutionGroup="gml:_CoordinateSystem"/>
<complexType name="ObliqueCartesianCSType">
  <complexContent>
    <extension base="gml:AbstractCoordinateSystemType"/>
  </complexContent>
</complexType>
```

```

</complexContent>
</complexType>

```

A two- or three-dimensional coordinate system with straight axes that are not necessarily orthogonal. An ObliqueCartesianCS shall have two or three usesAxis associations.

#### 12.4.4.20 gml:obliqueCartesianCSRef

```

<element name="obliqueCartesianCSRef" type="gml:ObliqueCartesianCSRefType"
  substitutionGroup="gml:coordinateSystemRef"/>

<complexType name="ObliqueCartesianCSRefType">
  <complexContent>
    <restriction base="gml:CoordinateSystemRefType">
      <sequence>
        <element ref="gml:ObliqueCartesianCS" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to an oblique-Cartesian coordinate system, either referencing or containing the definition of that coordinate system.

## 12.5 datums schema

### 12.5.1 Overview

#### 12.5.1.1 Introduction

A datum specifies the relationship of a coordinate system to the earth, or to a moving platform in some Engineering CRSs, thus creating a coordinate reference system. A datum can be used as the basis for one-, two- or three-dimensional systems. Five types of datum are specified: geodetic, vertical, engineering, image, and temporal.

#### 12.5.1.2 Geodetic datum

A geodetic datum is used by a geographic or geocentric CRS, and combines an ellipsoid with a prime meridian. The ellipsoid is used to approximate the shape of the earth, as discussed above in Subclause 12.1.3 and below. A prime meridian defines the origin from which longitude values are specified. Most geodetic datums use Greenwich as their prime meridian.

An ellipsoid is defined to approximate the surface of the geoid. The area for which the approximation is valid varies – traditionally regionally, but with the advent of satellite positioning often globally. One ellipsoid shall be specified with every geodetic datum, even if the ellipsoid is not used computationally. The latter may be the case when a Geocentric CRS is used, e.g., in the calculation of satellite orbit and ground positions from satellite observations. Although use of a Geocentric CRS apparently obviates the need of an ellipsoid, the ellipsoid usually played a role in the determination of the associated geodetic datum.

An ellipsoid is defined either by its semi-major axis and inverse flattening, or by its semi-major axis and semi-minor axis. For some applications, for example small-scale mapping in atlases, a spherical approximation of the geoid's surface is used, requiring only the radius of the sphere to be specified. In the XML Schema, these options are modelled by a mandatory element "semiMajorAxis", plus a "secondDefiningParameter" element. That element allows specification of the semiMinorAxis or inverseFlattening as the second defining ellipsoid parameter, or can specify that a spherical model is used. For a sphere, the "semiMajorAxis" is interpreted as the radius of the sphere.

### 12.5.1.3 Vertical datum

A vertical datum can only be associated with a vertical coordinate reference system. Further sub-typing is required to describe vertical datums adequately. The following types of vertical datum are distinguished:

- a) **Geoidal.** The zero value of the associated (vertical) coordinate system axis is defined to approximate a constant potential surface, usually the geoid. Such a reference surface is usually determined by a national or scientific authority and is then a well-known, named datum. This is the default vertical datum type, because it is the most common one encountered.
- b) **Depth.** The zero point of the vertical axis is defined by a surface that has meaning for the purpose the associated vertical measurements are used for. For hydrographic charts, this is often a predicted nominal sea surface (i.e., without waves or other wind and current effects) that occurs at low tide. Examples are Lowest Astronomical Tide and Lowest Low Water Spring. A different example is a sloping and undulating River Datum defined as the nominal river water surface occurring at a quantified river discharge.
- c) **Barometric.** A vertical datum is of type “barometric” if atmospheric pressure is the basis for the definition of the origin. Atmospheric pressure may be used as the intermediary to determine height (barometric height determination) or it may be used directly as the vertical ordinate, against which other parameters are measured. The latter case is applied routinely in meteorology.

Barometric height determination is routinely used in aircraft. The altimeter (barometer) on board is set to the altitude of the airfield at the time of take-off, which corrects simultaneously for instantaneous air pressure and altitude of the airfield. The measured height value is commonly named “altitude”.

In some land surveying applications, height differences between points are measured with barometers. To obtain absolute heights, the measured height differences are added to the known heights of control points. In that case the vertical datum type is not barometric, but is the same as that of the vertical control network used to obtain the heights of the new points and its vertical datum type.

The accuracy of this technique is limited, as it is affected strongly by the spatial and temporal variability of atmospheric pressure. This accuracy limitation impacts the precision of the associated vertical datum definition. The datum is usually the surface of constant atmospheric pressure approximately equating to mean sea level (MSL). The origin or anchor point is usually a point of known MSL height. The instruments are calibrated at this point by correcting for the instantaneous atmospheric pressure at sea level and the height of the point above MSL.

In meteorology, atmospheric pressure routinely takes the role of vertical ordinate in a CRS that is used as a spatial reference frame for meteorological parameters in the upper atmosphere. The origin of the datum is the (hypothetical) zero atmospheric pressure and the positive vertical axis points down (to increasing pressure).

- d) **Other surface.** In some cases, e.g. oil exploration and production, geological features, i.e., the top or bottom of a geologically identifiable and meaningful subsurface layer, are sometimes used as a vertical datum. Other variations to the above three vertical datum types may exist and are all bracketed in this category.

### 12.5.1.4 Image datum

An image datum is used in a local context, to describe the origin of an image coordinate reference system. The image grid is defined as the set of lines of constant integer ordinate values. The term “image grid” is often used in other standards to describe the concept of Image CRS. However, care shall be taken to correctly interpret this term in the context in which it is used. The term “grid cell” is often used as a substitute for the term “pixel”.

The grid lines of the image may be associated in two ways with data values of the pixel or grid cell (ISO 19123). The data values of the image usually represent an average or integrated value that is associated with the entire pixel.

- a) An image grid can be associated with data values such that the grid lines run through the centres of the pixels. The cell centres will thus have integer coordinate values. In this case the “pixel in cell” will have the value “cell centre”.
- b) Alternatively, the image grid may be defined such that the grid lines define the cell or pixel corners rather than the cell centres. The cell centres will thus have non-integer coordinate values, the fractional parts always being 0.5. ISO 19123 calls the grid points in this latter case “posts” and associated image data: “matrix data”. The “pixel in cell” will now have the value “cell corner”.

This difference in perspective has no effect on image interpretation, but is important for coordinate transformations involving this image.

### 12.5.1.5 Engineering datum

An engineering datum is used in a local context, to describe the origin of an engineering (or local) coordinate reference system.

### 12.5.1.6 Temporal datum

A temporal datum is used to describe the origin of a temporal coordinate reference system.

### 12.5.1.7 Schema introduction

The datums.xsd schema has three logical parts, which define elements and types for XML encoding of the definitions of:

- a) Abstract datum
- b) Geodetic datums, including ellipsoid and prime meridian
- c) Multiple other concrete types of spatial-temporal datums

This schema encodes the Datum package of the UML Model for OGC Abstract Specification Topic 2: Spatial Referencing by Coordinates. That UML model is adapted from ISO 19111 - Spatial referencing by coordinates, as described in Annex B of Topic 2.

The datums schema includes the referenceSystems.xsd GML schema. This schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd: datums:v3.1.0
```

## 12.5.2 Abstract datum

### 12.5.2.1 gml:\_Datum

```
<element name="_Datum" type="gml:AbstractDatumType" abstract="true" substitutionGroup="gml:Definition"/>
<complexType name="AbstractDatumType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractDatumBaseType">
      <sequence>
        <element ref="gml:datumID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:anchorPoint" minOccurs="0"/>
        <element ref="gml:realizationEpoch" minOccurs="0"/>
        <element ref="gml:validArea" minOccurs="0"/>
        <element ref="gml:scope" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

</complexType>

<complexType name="AbstractDatumBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:datumName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>

```

A datum specifies the relationship of a coordinate system to the earth, thus creating a coordinate reference system. A datum uses a parameter or set of parameters that determine the location of the origin of the coordinate reference system. Each datum subtype can be associated with only specific types of coordinate systems. This abstract complexType shall not be used, extended, or restricted, in an Application Schema, to define a concrete subtype with a meaning equivalent to a concrete subtype specified in this document.

The AbstractDatumBaseType provides the basic encoding for datum objects, simplifying and restricting the DefinitionType as needed.

The "datumID" elements contain a set of alternative identifications of this datum. The first datumID, if any, is normally the primary identification code, and any others are aliases.

The "remarks" element contains comments on or information about this reference system, including source information.

#### 12.5.2.2 gml:datumName

```
<element name="datumName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this datum is identified.

#### 12.5.2.3 gml:datumID

```
<element name="datumID" type="gml:IdentifierType"/>
```

An identification of a datum.

#### 12.5.2.4 gml:anchorPoint

```
<element name="anchorPoint" type="gml:CodeType"/>
```

Description, possibly including coordinates, of the point or points used to anchor the datum to the Earth. Also known as the "origin", especially for engineering and image datums. The codeSpace attribute can be used to reference a source of more detailed on this point or surface, or on a set of such descriptions.

- a) For a geodetic datum, this point is also known as the fundamental point, which is traditionally the point where the relationship between geoid and ellipsoid is defined. In some cases, the "fundamental point" may consist of a number of points. In those cases, the parameters defining the geoid/ellipsoid relationship have been averaged for these points, and the averages adopted as the datum definition.
- b) For an engineering datum, the anchor point may be a physical point, or it may be a point with defined coordinates in another CRS. When appropriate, the coordinates of this anchor point can be referenced in another document, such as referencing a GML feature that references or includes a point position.
- c) For an image datum, the anchor point is usually either the centre of the image or the corner of the image.

- d) For a temporal datum, this attribute is not defined. Instead of the anchor point, a temporal datum carries a separate time origin of type DateTime.

#### 12.5.2.5 gml:realizationEpoch

```
<element name="realizationEpoch" type="date"/>
```

The time after which this datum definition is valid. This time may be precise (e.g. 1997.0 for IRTF97) or merely a year (e.g. 1983 for NAD83). In the latter case, the epoch usually refers to the year in which a major recalculation of the geodetic control network, underlying the datum, was executed or initiated. An old datum can remain valid after a new datum is defined. Alternatively, a datum may be superseded by a later datum, in which case the realization epoch for the new datum defines the upper limit for the validity of the superseded datum.

#### 12.5.2.6 gml:datumRef

```
<element name="datumRef" type="gml:DatumRefType" substitutionGroup="gml:dictionaryEntry"/>  
  
<complexType name="DatumRefType">  
  <complexContent>  
    <restriction base="gml:DictionaryEntryType">  
      <sequence>  
        <element ref="gml:_Datum" minOccurs="0"/>  
      </sequence>  
      <attributeGroup ref="gml:AssociationAttributeGroup"/>  
    </restriction>  
  </complexContent>  
</complexType>
```

Association to a datum, either referencing or containing the definition of that datum.

### 12.5.3 Geodetic datum

#### 12.5.3.1 gml:GeodeticDatum

```
<element name="GeodeticDatum" type="gml:GeodeticDatumType" substitutionGroup="gml:_Datum"/>  
  
<complexType name="GeodeticDatumType">  
  <complexContent>  
    <extension base="gml:AbstractDatumType">  
      <sequence>  
        <element ref="gml:usesPrimeMeridian"/>  
        <element ref="gml:usesEllipsoid"/>  
      </sequence>  
    </extension>  
  </complexContent>  
</complexType>
```

A geodetic datum defines the precise location and orientation in 3-dimensional space of a defined ellipsoid (or sphere), or of a Cartesian coordinate system centered in this ellipsoid (or sphere).

#### 12.5.3.2 gml:usesPrimeMeridian

```
<element name="usesPrimeMeridian" type="gml:PrimeMeridianRefType"/>
```

Association to the prime meridian used by this geodetic datum.

#### 12.5.3.3 gml:usesEllipsoid

```
<element name="usesEllipsoid" type="gml:EllipsoidRefType"/>
```

Association to the ellipsoid used by this geodetic datum.

#### 12.5.3.4 gml:geodeticDatumRef

```
<element name="geodeticDatumRef" type="gml:GeodeticDatumRefType" substitutionGroup="gml:datumRef"/>
<complexType name="GeodeticDatumRefType">
  <complexContent>
    <restriction base="gml:DatumRefType">
      <sequence>
        <element ref="gml:GeodeticDatum" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a geodetic datum, either referencing or containing the definition of that datum.

#### 12.5.3.5 gml:Ellipsoid

```
<element name="Ellipsoid" type="gml:EllipsoidType" substitutionGroup="gml:Definition"/>
<complexType name="EllipsoidType">
  <complexContent>
    <extension base="gml:EllipsoidBaseType">
      <sequence>
        <element ref="gml:ellipsoidID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:semiMajorAxis"/>
        <element ref="gml:secondDefiningParameter"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<complexType name="EllipsoidBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:ellipsoidName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

An ellipsoid is a geometric figure that can be used to describe the approximate shape of the earth. In mathematical terms, it is a surface formed by the rotation of an ellipse about its minor axis.

The EllipsoidBaseType provides the basic encoding for ellipsoid objects, simplifying and restricting the DefinitionType as needed.

The "ellipsoidID" elements contain a set of alternative identifications of this ellipsoid. The first ellipsoidID, if any, is normally the primary identification code, and any others are aliases.

The "remarks" element contains comments on or information about this reference system, including source information.

### 12.5.3.6 gml:ellipsoidName

```
<element name="ellipsoidName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this ellipsoid is identified.

### 12.5.3.7 gml:ellipsoidID

```
<element name="ellipsoidID" type="gml:IdentifierType"/>
```

An identification of an ellipsoid.

### 12.5.3.8 gml:semiMajorAxis

```
<element name="semiMajorAxis" type="gml:LengthType"/>
```

Length of the semi-major axis of the ellipsoid.

### 12.5.3.9 gml:ellipsoidRef

```
<element name="ellipsoidRef" type="gml:EllipsoidRefType" substitutionGroup="gml:dictionaryEntry"/>  
  
<complexType name="EllipsoidRefType">  
  <complexContent>  
    <restriction base="gml:DictionaryEntryType">  
      <sequence>  
        <element ref="gml:Ellipsoid" minOccurs="0"/>  
      </sequence>  
      <attributeGroup ref="gml:AssociationAttributeGroup"/>  
    </restriction>  
  </complexContent>  
</complexType>
```

Association to an ellipsoid, either referencing or containing the definition of that ellipsoid.

### 12.5.3.10 gml:secondDefiningParameter

```
<element name="secondDefiningParameter" type="gml:SecondDefiningParameterType"/>  
  
<complexType name="SecondDefiningParameterType">  
  <choice>  
    <element ref="gml:inverseFlattening"/>  
    <element ref="gml:semiMinorAxis"/>  
    <element ref="gml:isSphere"/>  
  </choice>  
</complexType>
```

Definition of the second parameter that defines the shape of an ellipsoid. An ellipsoid requires two defining parameters: semi-major axis and inverse flattening or semi-major axis and semi-minor axis. When the reference body is a sphere rather than an ellipsoid, only a single defining parameter is required, namely the radius of the sphere; in that case, the semi-major axis "degenerates" into the radius of the sphere.

### 12.5.3.11 gml:inverseFlattening

```
<element name="inverseFlattening" type="gml:ScaleType"/>
```

Inverse flattening value of the ellipsoid

### 12.5.3.12 gml:semiMinorAxis

```
<element name="semiMinorAxis" type="gml:LengthType"/>
```

Length of the semi-minor axis of the ellipsoid.

### 12.5.3.13 gml:isSphere

```
<element name="isSphere">
  <simpleType>
    <restriction base="string">
      <enumeration value="sphere"/>
    </restriction>
  </simpleType>
</element>
```

When this element is included, the ellipsoid is degenerate and is actually a sphere. The sphere is completely defined by the semi-major axis, which is the radius of the sphere.

### 12.5.3.14 gml:PrimeMeridian

```
<element name="PrimeMeridian" type="gml:PrimeMeridianType" substitutionGroup="gml:Definition"/>
<complexType name="PrimeMeridianType">
  <complexContent>
    <extension base="gml:PrimeMeridianBaseType">
      <sequence>
        <element ref="gml:meridianID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:greenwichLongitude"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
<complexType name="PrimeMeridianBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:meridianName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

A prime meridian defines the origin from which longitude values are determined.

The PrimeMeridianBaseType provides the basic encoding for prime meridian objects, simplifying and restricting the DefinitionType as needed.

The "meridianID" elements contain a set of alternative identifications of this prime meridian. The first meridianID, if any, is normally the primary identification code, and any others are aliases.

The "remarks" element contains comments on or information about this reference system, including source information.

### 12.5.3.15 gml:meridianName

```
<element name="meridianName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this prime meridian is identified. The meridianName most common value is “Greenwich”, and that value shall be used when the greenwichLongitude value is zero.

#### 12.5.3.16 gml:meridianID

```
<element name="meridianID" type="gml:IdentifierType"/>
```

An identification of a prime meridian.

#### 12.5.3.17 gml:greenwichLongitude

```
<element name="greenwichLongitude" type="gml:AngleChoiceType"/>
```

Longitude of the prime meridian measured from the Greenwich meridian, positive eastward. The greenwichLongitude most common value is zero, and that value shall be used when the meridianName value is “Greenwich”.

#### 12.5.3.18 gml:primeMeridianRef

```
<element name="primeMeridianRef" type="gml:PrimeMeridianRefType" substitutionGroup="gml:dictionaryEntry"/>  
<complexType name="PrimeMeridianRefType">  
  <complexContent>  
    <restriction base="gml:DictionaryEntryType">  
      <sequence>  
        <element ref="gml:PrimeMeridian" minOccurs="0"/>  
      </sequence>  
      <attributeGroup ref="gml:AssociationAttributeGroup"/>  
    </restriction>  
  </complexContent>  
</complexType>
```

Association to a prime meridian, either referencing or containing the definition of that meridian.

### 12.5.4 Other concrete datums

#### 12.5.4.1 gml:EngineeringDatum

```
<element name="EngineeringDatum" type="gml:EngineeringDatumType" substitutionGroup="gml:_Datum"/>  
<complexType name="EngineeringDatumType">  
  <complexContent>  
    <extension base="gml:AbstractDatumType"/>  
  </complexContent>  
</complexType>
```

An engineering datum defines the origin of an engineering coordinate reference system, and is used in a region around that origin. This origin can be fixed with respect to the earth (such as a defined point at a construction site), or be a defined point on a moving vehicle (such as on a ship or satellite).

#### 12.5.4.2 gml:engineeringDatumRef

```
<element name="engineeringDatumRef" type="gml:EngineeringDatumRefType" substitutionGroup="gml:datumRef"/>  
<complexType name="EngineeringDatumRefType">  
  <complexContent>  
    <restriction base="gml:DatumRefType">  
      <sequence>  
        <element ref="gml:EngineeringDatum" minOccurs="0"/>  
      </sequence>  
    </restriction>  
  </complexContent>  
</complexType>
```

```

        <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
</complexContent>
</complexType>

```

Association to an engineering datum, either referencing or containing the definition of that datum.

### 12.5.4.3 gml:ImageDatum

```

<element name="ImageDatum" type="gml:ImageDatumType" substitutionGroup="gml:_Datum"/>
<complexType name="ImageDatumType">
  <complexContent>
    <extension base="gml:AbstractDatumType">
      <sequence>
        <element ref="gml:pixelInCell"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

An image datum defines the origin of an image coordinate reference system, and is used in a local context only. For more information, see Subclause 12.5.1.

### 12.5.4.4 gml:pixelInCell

```

<element name="pixelInCell" type="gml:PixelInCellType"/>
<complexType name="PixelInCellType">
  <simpleContent>
    <restriction base="gml:CodeType">
      <attribute name="codeSpace" type="anyURI" use="required"/>
    </restriction>
  </simpleContent>
</complexType>

```

Specification of the way an image grid is associated with the image data attributes. The required codeSpace attribute shall reference a source of information specifying the values and meanings of all the allowed string values for this PixelInCellType.

### 12.5.4.5 gml:imageDatumRef

```

<element name="imageDatumRef" type="gml:ImageDatumRefType" substitutionGroup="gml:datumRef"/>
<complexType name="ImageDatumRefType">
  <complexContent>
    <restriction base="gml:DatumRefType">
      <sequence>
        <element ref="gml:ImageDatum" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to an image datum, either referencing or containing the definition of that datum.

### 12.5.4.6 gml:VerticalDatum

```

<element name="VerticalDatum" type="gml:VerticalDatumType" substitutionGroup="gml:_Datum"/>
<complexType name="VerticalDatumType">
  <complexContent>

```

```

    <extension base="gml:AbstractDatumType">
      <sequence>
        <element ref="gml:verticalDatumType" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A textual description and/or a set of parameters identifying a particular reference level surface used as a zero-height surface, including its position with respect to the Earth for any of the height types recognized by this standard. There are several types of Vertical Datums, and each may place constraints on the Coordinate Axis with which it is combined to create a Vertical CRS.

#### 12.5.4.7 gml:verticalDatumType

```

<element name="verticalDatumType" type="gml:VerticalDatumTypeType"/>
<complexType name="VerticalDatumTypeType">
  <simpleContent>
    <restriction base="gml:CodeType">
      <attribute name="codeSpace" type="anyURI" use="required"/>
    </restriction>
  </simpleContent>
</complexType>

```

Type of a vertical datum. The required codeSpace attribute shall reference a source of information specifying the values and meanings of all the allowed string values for this VerticalDatumTypeType.

#### 12.5.4.8 gml:verticalDatumRef

```

<element name="verticalDatumRef" type="gml:VerticalDatumRefType" substitutionGroup="gml:datumRef"/>
<complexType name="VerticalDatumRefType">
  <complexContent>
    <restriction base="gml:DatumRefType">
      <sequence>
        <element ref="gml:VerticalDatum" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a vertical datum, either referencing or containing the definition of that datum.

#### 12.5.4.9 gml:TemporalDatum

```

<element name="TemporalDatum" type="gml:TemporalDatumType" substitutionGroup="gml:_Datum"/>
<complexType name="TemporalDatumType">
  <complexContent>
    <extension base="gml:TemporalDatumBaseType">
      <sequence>
        <element ref="gml:origin"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
<complexType name="TemporalDatumBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:AbstractDatumType">
      <sequence>

```

```

        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:datumName"/>
        <element ref="gml:datumID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:validArea" minOccurs="0"/>
        <element ref="gml:scope" minOccurs="0"/>
    </sequence>
    <attribute ref="gml:id" use="required"/>
</restriction>
</complexContent>
</complexType>

```

A temporal datum defines the origin of a temporal coordinate reference system. This type extends the TemporalDatumRestrictionType to add the "origin" element with the dateTime type.

The TemporalDatumBaseType partially defines the origin of a temporal coordinate reference system. This type restricts the AbstractDatumType to remove the "anchorPoint" and "realizationEpoch" elements.

#### 12.5.4.10 gml:origin

```
<element name="origin" type="dateTime"/>
```

The date and time origin of this temporal datum.

#### 12.5.4.11 gml:temporalDatumRef

```

<element name="temporalDatumRef" type="gml:TemporalDatumRefType" substitutionGroup="gml:datumRef"/>
<complexType name="TemporalDatumRefType">
    <complexContent>
        <restriction base="gml:DatumRefType">
            <sequence>
                <element ref="gml:TemporalDatum" minOccurs="0"/>
            </sequence>
            <attributeGroup ref="gml:AssociationAttributeGroup"/>
        </restriction>
    </complexContent>
</complexType>

```

Association to a temporal datum, either referencing or containing the definition of that datum.

## 12.6 coordinateOperations schema

### 12.6.1 Overview

#### 12.6.1.1 Introduction

A coordinate operation defines the coordinate transformation or conversion between coordinates in two different coordinate reference systems. Provided the relationship between any two coordinate reference systems is known, coordinates can be transformed or converted to another coordinate reference system.

A coordinate operation therefore usually specifies a source and target coordinate reference system. For that reason a coordinate operation is often popularly said to operate between two coordinate reference systems. Although this wording may be good enough for conversation, it must be realised that coordinate operations do not operate on coordinate reference systems, but on coordinates. This fact is important because of its implication that coordinate reference systems cannot be 'created' from another coordinate reference system by means of a coordinate operation. Neither can a coordinate operation be used to modify the definition of a coordinate reference system, e.g., by converting the units of measure of the coordinates.

### 12.6.1.2 Coordinate operation types

Coordinate operations are divided into four types:

- a) Coordinate conversion – mathematical operation on coordinates that does not include any change of Datum. The best-known example of a coordinate conversion is a map projection. The parameters describing coordinate conversions are defined rather than empirically derived. Please note that some conversions have no parameters.
- b) Coordinate transformation – mathematical operation on coordinates that includes a change of Datum. The parameters of a coordinate transformation are empirically derived from a dataset containing the coordinates of a series of points in both coordinate reference systems. This computational process is usually ‘overdetermined’, allowing derivation of error (or accuracy) estimates for the transformation. Also, the stochastic nature of the parameters may result in multiple (different) instantiations of the same coordinate transformation.
- c) Concatenated operation – sequential application of two or more coordinate transformations and/or conversions.
- d) Pass through operation – application of a specified coordinate conversion or transformation to convert a subset of the coordinates of a compound CRS.

A coordinate transformation or conversion can be time-varying, and shall be time-varying if either the source or target CRS is time varying. When the coordinate operation is time-varying, the operation method used will also be time-varying, and some of the parameters used by that operation method will involve time. For example, some of the parameters may have time, speed, and/or acceleration values and units. The variables used in the operation method algorithm may include time explicitly or only implicitly (for example, time may be an unspecified function of other variables).

### 12.6.1.3 Coordinate conversions

Coordinate conversions are coordinate operations that make use of exact, defined (rather than measured or computed), and therefore error-free parameter values. Corresponding pairs of coordinate tuples in each of the two coordinate reference systems connected through a coordinate conversion have a fixed arithmetic relationship. Additionally one of the two tuples cannot exist without specification of the coordinate conversion and the ‘source’ coordinate reference system. Coordinate conversions are therefore intimately related to the earlier-defined concept of Derived CRSs.

The best-known example of this source-derived relationship is a projected coordinate reference system, which is always based on a source geographic coordinate reference system. The associated map projection effectively defines the projected coordinate reference system from the geographic coordinate system. This concept is modelled as a direct link between coordinate reference system and coordinate conversion.

Please note that this does not contradict the statement above that a coordinate operation cannot be used to create or modify a coordinate reference system in a software implementation. The text above describes a static source-result relationship between coordinates in the two coordinate reference systems. For such defining coordinate conversions, no source and target coordinate reference system are defined. The usage of such a coordinate conversion is in the coordinate reference system, which will point to that conversion and to its source coordinate reference system.

The source and target coordinate reference system of a coordinate conversion are defined in the GeneralDerivedCRS, by specifying the base (i.e., source) CRS and the defining conversion. The derived coordinate reference system itself is the target CRS in this situation.

### 12.6.1.4 Concatenated coordinate operation

A concatenated coordinate operation is an ordered sequence of coordinate operations. The sequence of operations is constrained by the requirement that the source coordinate reference system of step  $(n+1)$  shall

be the same as the target coordinate reference system of step ( $n$ ). The source coordinate reference system of the first step and the target coordinate reference system of the last step are the source and target coordinate reference system associated with the concatenated operation.

The above constraint should not be interpreted as implying that only those coordinate operations can be used in a concatenated operation that have their source and a target coordinate reference system specified through the association pair between a `CoordinateOperation` and a CRS. This would exclude coordinate conversions. Concatenated coordinate operations may contain coordinate transformations and/or coordinate conversions. When used in a concatenated operation, the conversion's source and target coordinate reference system are equally subject to the above constraint as the source and target of a transformation although they are specified in a different manner.

#### 12.6.1.5 Pass-through coordinate operation

Coordinate operations require input coordinate tuples of certain dimensions, and produce output tuples of certain dimensions. The dimensions of these coordinate tuples and the dimensions of the coordinate reference system they are defined in shall be the same.

The ability to define compound coordinate reference systems combining two or more other coordinate reference systems, not themselves compound, introduces a difficulty. For example, it may be required to transform only the horizontal or only the vertical component of a compound coordinate reference system, which will put them at odds with coordinate operations specified for either horizontal or vertical coordinates only. To the human mind this is a trivial problem, but not so for coordinate transformation software that ought to be capable of automatic operation, without human intervention. The software logic would be confronted with the problem of having to apply a 2-dimensional coordinate operation to 3-dimensional coordinate tuples.

This problem has been solved by defining a pass-through operation. This operation specifies what subset of a coordinate tuple is subject to a requested transformation. It takes the form of referencing another coordinate operation and specifying a sequence of numbers defining the positions in the coordinate tuple of the coordinates affected by that transformation.

NOTE. The order of the coordinates in a coordinate tuple shall agree with the order of the coordinate system axes as defined for the associated coordinate system.

#### 12.6.1.6 Operation method and parameters

The algorithm used to execute the coordinate operation is defined in the operation method. Concatenated operations and pass-through operations do not require a coordinate operation to be specified. Each operation method uses a number of parameters (although some coordinate conversions use none), and each coordinate operation assigns value to these parameters.

Most parameter values are numeric, but for some operation methods, notably those implementing a grid interpolation algorithm, the parameter value could be a file name and location (this may be a URI). An example is the coordinate transformation from NAD 27 to NAD 83 in the USA; depending on the locations of the points to be transformed, one of a series of grid files should be used.

As this class comes close to the heart of any coordinate transformation software, it is recommended to make extensive use of identifiers, referencing well-known datasets wherever possible. There is as yet no standard way of spelling or even naming the various coordinate operation methods. Client software requesting a coordinate operation to be executed by a coordinate transformation server implementation may therefore ask for an operation method this server doesn't recognise, although a perfectly valid method may be available. The same holds for coordinate operation parameters used by any coordinate operation method.

To facilitate recognition and validation, the operation formulae shall be included or referenced in an operation method, and if possible a worked example.

Some operation methods may require a large number of operation parameters. Also, some operation methods require that groups of parameters be repeatable as a group. In such cases, it is helpful to group related parameters in parameter groups. Two or more parameter groups are then associated with a particular

coordinate operation method, and each parameter group consists of a set of operation parameters, or of other nested parameter groups. This way of modelling is not mandatory; all operation parameters can be directly associated with the operation method.

### 12.6.1.7 Schema introduction

The spatial-temporal coordinate operations schema, coordinateOperations.xsd, has five logical parts, which define elements and types for XML encoding of the definitions of:

- a) Multiple abstract coordinate operations
- b) Multiple concrete types of coordinate operations, including Transformations and Conversions
- c) Abstract and concrete parameter values and groups
- d) Operation methods
- e) Abstract and concrete operation parameters and groups

This schema encodes the Coordinate Operation package of the UML Model for OGC Abstract Specification Topic 2: Spatial Referencing by Coordinates. That UML model is adapted from ISO 19111 - Spatial referencing by coordinates, as described in Annex B of Topic 2.

The coordinateOperations schema includes the coordinateReferenceSystems.xsd and dataQuality.xsd GML schemas. This schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:coordinateOperations:v3.1.0
```

## 12.6.2 Abstract coordinate operations

### 12.6.2.1 gml:\_CoordinateOperation

```
<element name="_CoordinateOperation" type="gml:AbstractCoordinateOperationType" abstract="true"
substitutionGroup="gml:Definition"/>

<complexType name="AbstractCoordinateOperationType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractCoordinateOperationBaseType">
      <sequence>
        <element ref="gml:coordinateOperationID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:operationVersion" minOccurs="0"/>
        <element ref="gml:validArea" minOccurs="0"/>
        <element ref="gml:scope" minOccurs="0"/>
        <element ref="gml:_positionalAccuracy" minOccurs="0"/>
        <element ref="gml:sourceCRS" minOccurs="0"/>
        <element ref="gml:targetCRS" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<complexType name="AbstractCoordinateOperationBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:coordinateOperationName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

```
</complexContent>
</complexType>
```

A mathematical operation on coordinates that transforms or converts coordinates to another coordinate reference system. Many but not all coordinate operations (from CRS A to CRS B) also uniquely define the inverse operation (from CRS B to CRS A). In some cases, the operation method algorithm for the inverse operation is the same as for the forward algorithm, but the signs of some operation parameter values shall be reversed. In other cases, different algorithms are required for the forward and inverse operations, but the same operation parameter values are used. If (some) entirely different parameter values are needed, a different coordinate operation shall be defined.

The `AbstractCoordinateOperationBaseType` provides the basic encoding for coordinate operation objects, simplifying and restricting the `DefinitionType` as needed.

The optional `_positionalAccuracy` elements provide an unordered set of estimates of the impact of this coordinate operation on point position accuracy. This element provides position error estimates for target coordinates of this coordinate operation, assuming no errors in source coordinates.

The "coordinateOperationID" elements contain a set of alternative identifications of this coordinate operation. The first coordinateOperationID, if any, is normally the primary identification code, and any others are aliases.

The "remarks" element contains comments on or information about this reference system, including source information.

#### 12.6.2.2 gml:coordinateOperationName

```
<element name="coordinateOperationName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this coordinate operation is identified.

#### 12.6.2.3 gml:coordinateOperationID

```
<element name="coordinateOperationID" type="gml:IdentifierType"/>
```

An identification of a coordinate operation.

#### 12.6.2.4 gml:operationVersion

```
<element name="operationVersion" type="string"/>
```

Version of the coordinate transformation (i.e., instantiation due to the stochastic nature of the parameters). Mandatory when describing a transformation, and should not be supplied for a conversion.

#### 12.6.2.5 gml:sourceCRS

```
<element name="sourceCRS" type="gml:CRSRefType"/>
```

Association to the source CRS (coordinate reference system) of this coordinate operation.

#### 12.6.2.6 gml:targetCRS

```
<element name="targetCRS" type="gml:CRSRefType"/>
```

Association to the target CRS (coordinate reference system) of this coordinate operation. For constraints on multiplicity of "sourceCRS" and "targetCRS", see Subclause 12.6.1.

#### 12.6.2.7 gml:coordinateOperationRef

```
<element name="coordinateOperationRef" type="gml:CoordinateOperationRefType"/>
```

```

substitutionGroup="gml:dictionaryEntry"/>

<complexType name="CoordinateOperationRefType">
  <complexContent>
    <restriction base="gml:DictionaryEntryType">
      <sequence>
        <element ref="gml:_CoordinateOperation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a coordinate operation, either referencing or containing the definition of that coordinate operation.

#### 12.6.2.8 gml:\_SingleOperation

```

<element name="_SingleOperation" type="gml:AbstractSingleOperationType" abstract="true"
substitutionGroup="gml:_CoordinateOperation"/>

<complexType name="AbstractSingleOperationType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractCoordinateOperationType"/>
  </complexContent>
</complexType>

```

A single (not concatenated) coordinate operation.

#### 12.6.2.9 gml:singleOperationRef

```

<element name="singleOperationRef" type="gml:SingleOperationRefType"
substitutionGroup="gml:coordinateOperationRef"/>

<complexType name="SingleOperationRefType">
  <complexContent>
    <restriction base="gml:CoordinateOperationRefType">
      <sequence>
        <element ref="gml:_SingleOperation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a single operation, either referencing or containing the definition of that single operation.

#### 12.6.2.10 gml:\_Operation

```

<element name="_Operation" type="gml:AbstractOperationType" abstract="true"
substitutionGroup="gml:_SingleOperation"/>

<complexType name="AbstractOperationType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractSingleOperationType"/>
  </complexContent>
</complexType>

```

A parameterized mathematical operation on coordinates that transforms or converts coordinates to another coordinate reference system. This coordinate operation uses an operation method, usually with associated parameter values. However, operation methods and parameter values are directly associated with concrete subtypes, not with this abstract type.

This abstract complexType shall not be directly used, extended, or restricted in a compliant Application Schema.

#### 12.6.2.11 gml:operationRef

```
<element name="operationRef" type="gml:OperationRefType" substitutionGroup="gml:singleOperationRef"/>

<complexType name="OperationRefType">
  <complexContent>
    <restriction base="gml:SingleOperationRefType">
      <sequence>
        <element ref="gml:_Operation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to an abstract operation, either referencing or containing the definition of that operation.

#### 12.6.2.12 gml:\_GeneralConversion

```
<element name="_GeneralConversion" type="gml:AbstractGeneralConversionType" abstract="true"
substitutionGroup="gml:_Operation"/>

<complexType name="AbstractGeneralConversionType" abstract="true">
  <complexContent>
    <restriction base="gml:AbstractOperationType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:coordinateOperationName"/>
        <element ref="gml:coordinateOperationID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:validArea" minOccurs="0"/>
        <element ref="gml:scope" minOccurs="0"/>
        <element ref="gml:_positionalAccuracy" minOccurs="0"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

An abstract operation on coordinates that does not include any change of datum. The best-known example of a coordinate conversion is a map projection. The parameters describing coordinate conversions are defined rather than empirically derived. Note that some conversions have no parameters.

This abstract complexType is expected to be extended for well-known operation methods with many Conversion instances, in Application Schemas that define operation-method-specialized element names and contents. This conversion uses an operation method, usually with associated parameter values. However, operation methods and parameter values are directly associated with concrete subtypes, not with this abstract type. All concrete types derived from this type shall extend this type to include a "usesMethod" element that references the "OperationMethod" element. Similarly, all concrete types derived from this type shall extend this type to include zero or more elements each named "uses...Value" that each use the type of an element substitutable for the "\_generalParameterValue" element.

#### 12.6.2.13 gml:generalConversionRef

```
<element name="generalConversionRef" type="gml:GeneralConversionRefType"
substitutionGroup="gml:operationRef"/>

<complexType name="GeneralConversionRefType">
  <complexContent>
    <restriction base="gml:OperationRefType">
```

```

        <sequence>
          <element ref="gml:_GeneralConversion" minOccurs="0"/>
        </sequence>
        <attributeGroup ref="gml:AssociationAttributeGroup"/>
      </restriction>
    </complexContent>
  </complexType>

```

Association to a general conversion, either referencing or containing the definition of that conversion.

#### 12.6.2.14 gml:\_GeneralTransformation

```

<element name="_GeneralTransformation" type="gml:AbstractGeneralTransformationType" abstract="true"
  substitutionGroup="gml:_Operation"/>

<complexType name="AbstractGeneralTransformationType" abstract="true">
  <complexContent>
    <restriction base="gml:AbstractOperationType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:coordinateOperationName"/>
        <element ref="gml:coordinateOperationID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:operationVersion"/>
        <element ref="gml:validArea" minOccurs="0"/>
        <element ref="gml:scope" minOccurs="0"/>
        <element ref="gml:_positionalAccuracy" minOccurs="0"/>
        <element ref="gml:sourceCRS"/>
        <element ref="gml:targetCRS"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>

```

An abstract operation on coordinates that usually includes a change of Datum. The parameters of a coordinate transformation are empirically derived from data containing the coordinates of a series of points in both coordinate reference systems. This computational process is usually "over-determined", allowing derivation of error (or accuracy) estimates for the transformation. Also, the stochastic nature of the parameters may result in multiple (different) versions of the same coordinate transformation.

This abstract complexType is expected to be extended for well-known operation methods with many Transformation instances, in Application Schemas that define operation-method-specialized value element names and contents. This transformation uses an operation method with associated parameter values. However, operation methods and parameter values are directly associated with concrete subtypes, not with this abstract type. All concrete types derived from this type shall extend this type to include a "usesMethod" element that references one "OperationMethod" element. Similarly, all concrete types derived from this type shall extend this type to include one or more elements each named "uses...Value" that each use the type of an element substitutable for the "\_generalParameterValue" element.

#### 12.6.2.15 gml:generalTransformationRef

```

<element name="generalTransformationRef" type="gml:GeneralTransformationRefType"
  substitutionGroup="gml:operationRef"/>

<complexType name="GeneralTransformationRefType">
  <complexContent>
    <restriction base="gml:OperationRefType">
      <sequence>
        <element ref="gml:_GeneralTransformation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

```

    </restriction>
  </complexContent>
</complexType>

```

Association to a general transformation, either referencing or containing the definition of that transformation.

### 12.6.3 Concrete coordinate operations

#### 12.6.3.1 gml:ConcatenatedOperation

```

<element name="ConcatenatedOperation" type="gml:ConcatenatedOperationType"
  substitutionGroup="gml:_CoordinateOperation"/>

<complexType name="ConcatenatedOperationType">
  <complexContent>
    <extension base="gml:AbstractCoordinateOperationType">
      <sequence>
        <element ref="gml:usesSingleOperation" minOccurs="2" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A concatenated operation is an ordered sequence of two or more single coordinate operations. The sequence of operations is constrained by the requirement that the source coordinate reference system of step (n+1) shall be the same as the target coordinate reference system of step (n). The source coordinate reference system of the first step and the target coordinate reference system of the last step are the source and target coordinate reference system associated with the concatenated operation. Instead of a forward operation, an inverse operation may be used for one or more of the operation steps mentioned above, if the inverse operation is uniquely defined by the forward operation.

The usesSingleOperation elements are an ordered sequence of associations to the two or more single operations used by this concatenated operation.

#### 12.6.3.2 gml:usesSingleOperation

```

<element name="usesSingleOperation" type="gml:SingleOperationRefType"/>

```

Association to a single operation.

#### 12.6.3.3 gml:concatenatedOperationRef

```

<element name="concatenatedOperationRef" type="gml:ConcatenatedOperationRefType"
  substitutionGroup="gml:coordinateOperationRef"/>

<complexType name="ConcatenatedOperationRefType">
  <complexContent>
    <restriction base="gml:CoordinateOperationRefType">
      <sequence>
        <element ref="gml:ConcatenatedOperation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a concatenated operation, either referencing or containing the definition of that concatenated operation.

#### 12.6.3.4 gml:PassThroughOperation

```

<element name="PassThroughOperation" type="gml:PassThroughOperationType"

```

```

substitutionGroup="gml:_SingleOperation"/>
<complexType name="PassThroughOperationType">
  <complexContent>
    <extension base="gml:AbstractSingleOperationType">
      <sequence>
        <element ref="gml:modifiedCoordinate" maxOccurs="unbounded"/>
        <element ref="gml:usesOperation"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A pass-through operation specifies that a subset of a coordinate tuple is subject to a specific coordinate operation.

The modifiedCoordinate elements are an ordered sequence of positive integers defining the positions in a coordinate tuple of the coordinates affected by this pass-through operation.

#### 12.6.3.5 gml:modifiedCoordinate

```
<element name="modifiedCoordinate" type="positiveInteger"/>
```

#### 12.6.3.6 A positive integer defining a position in a coordinate tuple.gml:usesOperation

```
<element name="usesOperation" type="gml:OperationRefType"/>
```

Association to the operation applied to the specified ordinates.

#### 12.6.3.7 gml:passThroughOperationRef

```

<element name="passThroughOperationRef" type="gml:PassThroughOperationRefType"
substitutionGroup="gml:singleOperationRef"/>
<complexType name="PassThroughOperationRefType">
  <complexContent>
    <restriction base="gml:SingleOperationRefType">
      <sequence>
        <element ref="gml:PassThroughOperation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to a pass through operation, either referencing or containing the definition of that pass through operation.

#### 12.6.3.8 gml:Conversion

```

<element name="Conversion" type="gml:ConversionType" substitutionGroup="gml:_GeneralConversion"/>
<complexType name="ConversionType">
  <complexContent>
    <extension base="gml:AbstractGeneralConversionType">
      <sequence>
        <element ref="gml:usesMethod"/>
        <element ref="gml:usesValue" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A concrete operation on coordinates that does not include any change of Datum. The best-known example of a coordinate conversion is a map projection. The parameters describing coordinate conversions are defined rather than empirically derived. Note that some conversions have no parameters.

This concrete complexType can be used with all operation methods, without using an Application Schema that defines operation-method-specialized element names and contents, especially for methods with only one Conversion instance.

The usesValue elements are an unordered list of composition associations to the set of parameter values used by this conversion operation.

### 12.6.3.9 gml:usesMethod

```
<element name="usesMethod" type="gml:OperationMethodRefType"/>
```

Association to the operation method used by this coordinate operation.

### 12.6.3.10 gml:usesValue

```
<element name="usesValue" type="gml:ParameterValueType"/>
```

### 12.6.3.11 Composition association to a parameter value used by this coordinate operation.gml:conversionRef

```
<element name="conversionRef" type="gml:ConversionRefType" substitutionGroup="gml:generalConversionRef"/>
```

```
<complexType name="ConversionRefType">
  <complexContent>
    <restriction base="gml:GeneralConversionRefType">
      <sequence>
        <element ref="gml:Conversion" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a concrete general-purpose conversion, either referencing or containing the definition of that conversion.

### 12.6.3.12 gml:Transformation

```
<element name="Transformation" type="gml:TransformationType"
  substitutionGroup="gml:_GeneralTransformation"/>

<complexType name="TransformationType">
  <complexContent>
    <extension base="gml:AbstractGeneralTransformationType">
      <sequence>
        <element ref="gml:usesMethod"/>
        <element ref="gml:usesValue" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A concrete operation on coordinates that usually includes a change of datum. The parameters of a coordinate transformation are empirically derived from data containing the coordinates of a series of points in both coordinate reference systems. This computational process is usually "over-determined", allowing derivation of error (or accuracy) estimates for the transformation. Also, the stochastic nature of the parameters may result in multiple (different) versions of the same coordinate transformation.

This concrete complexType can be used for operation methods, without using an Application Schema that defines operation-method-specialized element names and contents, especially for methods with only one Transformation instance.

The usesValue elements are an unordered list of composition associations to the set of parameter values used by this transformation operation.

### 12.6.3.13 gml:transformationRef

```
<element name="transformationRef" type="gml:TransformationRefType"
  substitutionGroup="gml:generalTransformationRef"/>

<complexType name="TransformationRefType">
  <complexContent>
    <restriction base="gml:GeneralTransformationRefType">
      <sequence>
        <element ref="gml:Transformation" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a transformation, either referencing or containing the definition of that transformation.

## 12.6.4 Parameter values and groups

### 12.6.4.1 gml:\_generalParameterValue

```
<element name="_generalParameterValue" type="gml:AbstractGeneralParameterValueType" abstract="true"/>

<complexType name="AbstractGeneralParameterValueType" abstract="true">
  <sequence/>
</complexType>
```

Abstract parameter value or group of parameter values.

This abstract complexType is expected to be extended and restricted for well-known operation methods with many instances, in Application Schemas that define operation-method-specialized element names and contents. Specific parameter value elements are directly contained in concrete subtypes, not in this abstract type. All concrete types derived from this type shall extend this type to include one "...Value" element with an appropriate type, which should be one of the element types allowed in the ParameterValueType. In addition, all derived concrete types shall extend this type to include a "valueOfParameter" element that references one element substitutable for the "OperationParameter" element.

### 12.6.4.2 gml:parameterValue

```
<element name="parameterValue" type="gml:ParameterValueType"
  substitutionGroup="gml:_generalParameterValue"/>

<complexType name="ParameterValueType">
  <complexContent>
    <extension base="gml:AbstractGeneralParameterValueType">
      <sequence>
        <choice>
          <element ref="gml:value"/>
          <element ref="gml:dmsAngleValue"/>
          <element ref="gml:stringValue"/>
          <element ref="gml:integerValue"/>
          <element ref="gml:booleanValue"/>
          <element ref="gml:valueList"/>
        </choice>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

        <element ref="gml:integerValueList"/>
        <element ref="gml:valueFile"/>
    </choice>
    <element ref="gml:valueOfParameter"/>
</sequence>
</extension>
</complexContent>
</complexType>

```

A parameter value, ordered sequence of values, or reference to a file of parameter values. This concrete complexType can be used for operation methods without using an Application Schema that defines operation-method-specialized element names and contents, especially for methods with only one instance. This complexType can be used, extended, or restricted for well-known operation methods, especially for methods with many instances.

#### 12.6.4.3 gml:value

```
<element name="value" type="gml:MeasureType"/>
```

Numeric value of an operation parameter, with its associated unit of measure.

#### 12.6.4.4 gml:dmsAngleValue

```
<element name="dmsAngleValue" type="gml:DMSAngleType"/>
```

Value of an angle operation parameter, in either degree-minute-second format or single value format.

#### 12.6.4.5 gml:stringValue

```
<element name="stringValue" type="string"/>
```

String value of an operation parameter. A string value does not have an associated unit of measure.

#### 12.6.4.6 gml:integerValue

```
<element name="integerValue" type="positiveInteger"/>
```

Positive integer value of an operation parameter, usually used for a count. An integer value does not have an associated unit of measure.

#### 12.6.4.7 gml:booleanValue

```
<element name="booleanValue" type="boolean"/>
```

Boolean value of an operation parameter. A Boolean value does not have an associated unit of measure.

#### 12.6.4.8 gml:valueList

```
<element name="valueList" type="gml:MeasureListType"/>
```

Ordered sequence of two or more numeric values of an operation parameter list, where each value has the same associated unit of measure. An element of this type contains a space-separated sequence of double values.

#### 12.6.4.9 gml:integerValueList

```
<element name="integerValueList" type="gml:integerList"/>
```

Ordered sequence of two or more integer values of an operation parameter list, usually used for counts. These integer values do not have an associated unit of measure. An element of this type contains a space-separated sequence of integer values.

#### 12.6.4.10 gml:valueFile

```
<element name="valueFile" type="anyURI"/>
```

Reference to a file or a part of a file containing one or more parameter values, each numeric value with its associated unit of measure. When referencing a part of a file, that file shall contain multiple identified parts, such as an XML encoded document. Furthermore, the referenced file or part of a file can reference another part of the same or different files, as allowed in XML documents.

#### 12.6.4.11 gml:valueOfParameter

```
<element name="valueOfParameter" type="gml:OperationParameterRefType"/>
```

Association to the operation parameter that this is a value of.

#### 12.6.4.12 gml:parameterValueGroup

```
<element name="parameterValueGroup" type="gml:ParameterValueGroupType"
substitutionGroup="gml:_generalParameterValue"/>

<complexType name="ParameterValueGroupType">
  <complexContent>
    <extension base="gml:AbstractGeneralParameterValueType">
      <sequence>
        <element ref="gml:includesValue" minOccurs="2" maxOccurs="unbounded"/>
        <element ref="gml:valuesOfGroup"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A group of related parameter values. The same group can be repeated more than once in a Conversion, Transformation, or higher level parameterValueGroup, if those instances contain different values of one or more parameterValues which suitably distinguish among those groups. This concrete complexType can be used for operation methods without using an Application Schema that defines operation-method-specialized element names and contents. This complexType can be used, extended, or restricted for well-known operation methods, especially for methods with only one instance.

The includesValue elements are an unordered set of composition associations to the parameter values and groups of values included in this group.

#### 12.6.4.13 gml:includesValue

```
<element name="includesValue" type="gml:AbstractGeneralParameterValueType"
substitutionGroup="gml:_generalParameterValue"/>
```

A composition association to a parameter value or group of values included in this group.

#### 12.6.4.14 gml:valuesOfGroup

```
<element name="valuesOfGroup" type="gml:OperationParameterGroupRefType"/>
```

Association to the operation parameter group for which this element provides parameter values.

## 12.6.5 Operation method

### 12.6.5.1 gml:OperationMethod

```

<element name="OperationMethod" type="gml:OperationMethodType" substitutionGroup="gml:Definition"/>
<complexType name="OperationMethodType">
  <complexContent>
    <extension base="gml:OperationMethodBaseType">
      <sequence>
        <element ref="gml:methodID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:methodFormula"/>
        <element ref="gml:usesParameter" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
<complexType name="OperationMethodBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:DefinitionType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:methodName"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>

```

Definition of an algorithm used to perform a coordinate operation. Most operation methods use a number of operation parameters, although some coordinate conversions use none. Each coordinate operation using the method assigns values to these parameters.

The methodID elements contain a set of alternative identifications of this operation method. The first methodID, if any, is normally the primary identification code, and any others are aliases.

The usesParameter elements are an unordered list of associations to the set of operation parameters and parameter groups used by this operation method.

The OperationMethodBaseType provides the basic encoding for operation method objects, simplifying and restricting the DefinitionType as needed.

The "remarks" element contains comments on or information about this reference system, including source information.

### 12.6.5.2 gml:methodName

```

<element name="methodName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>

```

The name by which an operation method is identified.

### 12.6.5.3 gml:methodID

```

<element name="methodID" type="gml:IdentifierType"/>

```

An identification of this operation method.

### 12.6.5.4 gml:methodFormula

```

<element name="methodFormula" type="gml:CodeType"/>

```

Formula(s) used by this operation method. The value may be a reference to a publication. Note that the operation method may not be analytic, in which case this element references or contains the procedure, not an analytic formula.

#### 12.6.5.5 gml:sourceDimensions

```
<element name="sourceDimensions" type="positiveInteger"/>
```

Number of dimensions in the source CRS of this operation method.

#### 12.6.5.6 gml:targetDimensions

```
<element name="targetDimensions" type="positiveInteger"/>
```

Number of dimensions in the target CRS of this operation method

#### 12.6.5.7 gml:usesParameter

```
<element name="usesParameter" type="gml:AbstractGeneralOperationParameterRefType"/>
```

Association to an operation parameter or parameter group used by this operation method.

#### 12.6.5.8 gml:operationMethodRef

```
<element name="operationMethodRef" type="gml:OperationMethodRefType"
substitutionGroup="gml:dictionaryEntry"/>
```

```
<complexType name="OperationMethodRefType">
  <complexContent>
    <restriction base="gml:DictionaryEntryType">
      <sequence>
        <element ref="gml:OperationMethod" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to a concrete general-purpose operation method, either referencing or containing the definition of that method.

### 12.6.6 Operation parameters and groups

#### 12.6.6.1 gml:GeneralOperationParameter

```
<element name="_GeneralOperationParameter" type="gml:AbstractGeneralOperationParameterType"
abstract="true" substitutionGroup="gml:Definition"/>
```

```
<complexType name="AbstractGeneralOperationParameterType" abstract="true">
  <complexContent>
    <extension base="gml:DefinitionType">
      <sequence>
        <element ref="gml:minimumOccurs" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

Abstract definition of a parameter or group of parameters used by an operation method.

### 12.6.6.2 gml:minimumOccurs

```
<element name="minimumOccurs" type="nonNegativeInteger"/>
```

The minimum number of times that values for this parameter group or parameter are required. If this attribute is omitted, the minimum number is one.

### 12.6.6.3 gml:abstractGeneralOperationParameterRef

```
<element name="abstractGeneralOperationParameterRef" type="gml:AbstractGeneralOperationParameterRefType"
substitutionGroup="gml:dictionaryEntry"/>
```

```
<complexType name="AbstractGeneralOperationParameterRefType">
  <complexContent>
    <restriction base="gml:DictionaryEntryType">
      <sequence>
        <element ref="gml:_GeneralOperationParameter" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to an operation parameter or group, either referencing or containing the definition of that parameter or group.

### 12.6.6.4 gml:OperationParameter

```
<element name="OperationParameter" type="gml:OperationParameterType"
substitutionGroup="gml:_GeneralOperationParameter"/>
```

```
<complexType name="OperationParameterType">
  <complexContent>
    <extension base="gml:OperationParameterBaseType">
      <sequence>
        <element ref="gml:parameterID" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<complexType name="OperationParameterBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:AbstractGeneralOperationParameterType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:parameterName"/>
        <element ref="gml:minimumOccurs" minOccurs="0"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

The definition of a parameter used by an operation method. Most parameter values are numeric, but other types of parameter values are possible. This complexType is expected to be used or extended for all operation methods, without defining operation-method-specialized element names.

The OperationParameterBaseType provides the basic encoding for operation parameter objects, simplifying and restricting the DefinitionType as needed.

The parameterID elements contain a set of alternative identifications of this operation parameter. The first parameterID, if any, is normally the primary identification code, and any others are aliases.

The "remarks" element contains comments on or information about this reference system, including source information.

#### 12.6.6.5 gml:parameterName

```
<element name="parameterName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this operation parameter is identified.

#### 12.6.6.6 gml:parameterID

```
<element name="parameterID" type="gml:IdentifierType"/>
```

An identification of an operation parameter.

#### 12.6.6.7 gml:operationParameterRef

```
<element name="operationParameterRef" type="gml:OperationParameterRefType"/>
<complexType name="OperationParameterRefType">
  <complexContent>
    <restriction base="gml:AbstractGeneralOperationParameterRefType">
      <sequence>
        <element ref="gml:OperationParameter" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>
```

Association to an operation parameter, either referencing or containing the definition of that parameter.

#### 12.6.6.8 gml:OperationParameterGroup

```
<element name="OperationParameterGroup" type="gml:OperationParameterGroupType"
substitutionGroup="gml:_GeneralOperationParameter"/>
<complexType name="OperationParameterGroupType">
  <complexContent>
    <extension base="gml:OperationParameterGroupBaseType">
      <sequence>
        <element ref="gml:groupID" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:maximumOccurs" minOccurs="0"/>
        <element ref="gml:includesParameter" minOccurs="2" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
<complexType name="OperationParameterGroupBaseType" abstract="true">
  <complexContent>
    <restriction base="gml:AbstractGeneralOperationParameterType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:remarks" minOccurs="0"/>
        <element ref="gml:groupName"/>
        <element ref="gml:minimumOccurs" minOccurs="0"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

```

    </restriction>
  </complexContent>
</complexType>

```

The definition of a group of parameters used by an operation method. This complexType is expected to be used or extended for all applicable operation methods, without defining operation-method-specialized element names.

The OperationParameterGroupBaseType provides the basic encoding for operation parameter group objects, simplifying and restricting the DefinitionType as needed.

The "groupID" elements contain a set of alternative identifications of this operation parameter group. The first groupID, if any, is normally the primary identification code, and any others are aliases.

The includesParameter elements are an unordered list of associations to the set of operation parameters that are members of this group.

The "remarks" element contains comments on or information about this reference system, including source information.

### 12.6.6.9 gml:groupName

```
<element name="groupName" type="gml:SimpleNameType" substitutionGroup="gml:name"/>
```

The name by which this operation parameter group is identified.

### 12.6.6.10 gml:groupID

```
<element name="groupID" type="gml:IdentifierType"/>
```

An identification of an operation parameter group.

### 12.6.6.11 gml:maximumOccurs

```
<element name="maximumOccurs" type="positiveInteger"/>
```

The maximum number of times that values for this parameter group can be included. If this attribute is omitted, the maximum number is one.

### 12.6.6.12 gml:includesParameter

```
<element name="includesParameter" type="gml:AbstractGeneralOperationParameterRefType"/>
```

Association to an operation parameter that is a member of a group.

### 12.6.6.13 gml:operationParameterGroupRef

```

<element name="operationParameterGroupRef" type="gml:OperationParameterRefType"/>
<complexType name="OperationParameterGroupRefType">
  <complexContent>
    <restriction base="gml:AbstractGeneralOperationParameterRefType">
      <sequence>
        <element ref="gml:OperationParameterGroup" minOccurs="0"/>
      </sequence>
      <attributeGroup ref="gml:AssociationAttributeGroup"/>
    </restriction>
  </complexContent>
</complexType>

```

Association to an operation parameter, either referencing or containing the definition of that parameter.

## 12.7 dataQuality schema

### 12.7.1 Overview

Information about the accuracy or precision of coordinates, or of coordinate operations and coordinate operation parameters, is quality information and should be reported where possible in conformance with ISO 19115 and ISO 19114.

The parameters that define a coordinate reference system are chosen rather than measured to satisfy the degrees-of-freedom problem in the changeover from observation to coordinate quantities. Coordinate reference systems are therefore by definition error-free (i.e., non-stochastic). A coordinate reference system is realised through a network of control points. The coordinates of those control points, derived from surface and/or from satellite observations, are stochastic. Their accuracy can be expressed in a covariance matrix, which, due to the degrees-of-freedom problem, will have a rank deficiency, described in geodetic literature.

Coordinate transformations between coordinate reference systems usually have parameter values derived from two sets of point coordinates, one set in system 1, the other set in system 2. As these coordinates are stochastic (i.e., have random-error characteristics), the derived transformation parameter values will also be stochastic. Their covariance matrix can be calculated.

Coordinates that have not been 'naturally' determined in coordinate reference system 2, but have been determined in coordinate system 1 and then transformed to system 2, have the random error effects of the transformation superimposed on their original error characteristics. It may be possible in well-controlled cases to calculate the covariance matrices of the point coordinates before and after the transformation, and thus isolate the effect of the transformation, but in practice a user will only be interested in the accuracy of the final transformed coordinates.

Nevertheless the option is offered to specify the covariance matrix of point coordinates resulting exclusively from the transformation. It is outside the scope of this document to describe how that covariance matrix should be used. Because a covariance matrix is symmetrical, only the upper or lower diagonal part (including the main diagonal) needs to be specified.

For some transformations, this accuracy information is compacted in some assessment of an average impact on horizontal position and vertical position, allowing specification of average absolute accuracy and, when relevant and available, average relative accuracy. Hence separate quality measures may be specified for horizontal and for vertical position in those objects.

The data quality schema, dataQuality.xsd, specifies how to XML encode positional data quality information to describe the positional accuracy of coordinate operations. This schema encodes the Data Quality (DQ) package of the UML Model for OGC Abstract Specification Topic 2: Spatial Referencing by Coordinates. That UML model is adapted from ISO 19111 - Spatial referencing by coordinates, as described in Annex B of Topic 2.

The dataQuality schema includes the units.xsd GML schema. This schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:dataQuality:v3.1.0
```

### 12.7.2 All elements

#### 12.7.2.1 gml:\_positionalAccuracy

```
<element name="_positionalAccuracy" type="gml:AbstractPositionalAccuracyType" abstract="true"/>
<complexType name="AbstractPositionalAccuracyType" abstract="true">
  <sequence>
```

```

        <element ref="gml:measureDescription" minOccurs="0"/>
    </sequence>
</complexType>

```

Position error estimate (or accuracy) data.

### 12.7.2.2 gml:measureDescription

```
<element name="measureDescription" type="gml:CodeType"/>
```

A description of the position accuracy parameter(s) provided.

### 12.7.2.3 gml:absoluteExternalPositionalAccuracy

```

<element name="absoluteExternalPositionalAccuracy" type="gml:AbsoluteExternalPositionalAccuracyType"
substitutionGroup="gml:_positionalAccuracy"/>

<complexType name="AbsoluteExternalPositionalAccuracyType">
  <complexContent>
    <extension base="gml:AbstractPositionalAccuracyType">
      <sequence>
        <element ref="gml:result"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

Closeness of reported coordinate values to values accepted as or being true.

### 12.7.2.4 gml:relativeInternalPositionalAccuracy

```

<element name="relativeInternalPositionalAccuracy" type="gml:RelativeInternalPositionalAccuracyType"
substitutionGroup="gml:_positionalAccuracy"/>

<complexType name="RelativeInternalPositionalAccuracyType">
  <complexContent>
    <extension base="gml:AbstractPositionalAccuracyType">
      <sequence>
        <element ref="gml:result"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

Closeness of the relative positions of two or more positions to their respective relative positions accepted as or being true.

### 12.7.2.5 gml:result

```
<element name="result" type="gml:MeasureType"/>
```

A quantitative result defined by the evaluation procedure used, and identified by the measureDescription.

### 12.7.2.6 gml:covarianceMatrix

```

<element name="covarianceMatrix" type="gml:CovarianceMatrixType"
substitutionGroup="gml:_positionalAccuracy"/>

<complexType name="CovarianceMatrixType">
  <complexContent>
    <extension base="gml:AbstractPositionalAccuracyType">
      <sequence>

```

```

        <element ref="gml:unitOfMeasure" maxOccurs="unbounded"/>
        <element ref="gml:includesElement" maxOccurs="unbounded"/>
    </sequence>
</extension>
</complexContent>
</complexType>

```

Error estimate covariance matrix.

The unitOfMeasure elements are an ordered sequence of units of measure, corresponding to the row and column index numbers of the covariance matrix, starting with row and column 1 and ending with row/column N. Each unit of measure is for the ordinate reflected in the relevant row and column of the covariance matrix.

The includesElement elements are an unordered set of elements in this covariance matrix. Because the covariance matrix is symmetrical, only the elements in upper or lower diagonal part (including the main diagonal) of the matrix need to be specified. Any zero valued covariance elements can be omitted

### 12.7.2.7 gml:includesElement

```

<element name="includesElement" type="gml:CovarianceElementType"/>

<complexType name="CovarianceElementType">
  <sequence>
    <element ref="gml:rowIndex"/>
    <element ref="gml:columnIndex"/>
    <element ref="gml:covariance"/>
  </sequence>
</complexType>

```

An element of a covariance matrix.

### 12.7.2.8 gml:rowIndex

```

<element name="rowIndex" type="positiveInteger"/>

```

Row number of this covariance element value.

### 12.7.2.9 gml:columnIndex

```

<element name="columnIndex" type="positiveInteger"/>

```

Column number of this covariance element value.

### 12.7.2.10 gml:covariance

```

<element name="covariance" type="double"/>

```

Value of covariance matrix element.

## 13 GML schemas – topology

### 13.1 Introduction

Topology is the branch of mathematics describing the properties of objects which are invariant under continuous deformation. For example, a circle is topologically equivalent to an ellipse because one can be transformed into the other by stretching. In geographic modelling, the foremost use of topology is in accelerating computational geometry. The constructs of topology allow characterisation of the spatial relationships between objects using simple combinatorial or algebraic algorithms. Topology, realised by the

appropriate geometry, also allows a compact and unambiguous mechanism for expressing shared geometry among geographic features.

## 13.2 Topology Model

The conceptual model underlying the representation of topology in GML is that of Topic 1 of the OGC Abstract Specification (ISO 19107). The model describes the correspondence of topological and geometric relationships up to 3 dimensions – volume topology. Relevant parts of the model are summarised here for convenience.

There are four instantiable classes of primitive topology objects, one for each dimension up to 3D. In addition, topological complexes are supported, too.

There is strong symmetry in the (topological boundary and coboundary) relationships between topology primitives of adjacent dimensions. Topology primitives are bounded by directed primitives of one lower dimension. The coboundary of each topology primitive is formed from directed topology primitives of one higher dimension.

## 13.3 Types and elements

### 13.3.1 Schema Includes

```
<include schemaLocation="geometryComplexes.xsd"/>
```

The topology schema includes definitions from the geometry schema yielding the ability to describe primitives and complexes with a geometric realisation.

### 13.3.2 gml:AbstractTopologyType, gml:\_Topology

```
<complexType name="AbstractTopologyType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGMLType"/>
  </complexContent>
</complexType>

<element name="_Topology" type="gml:AbstractTopologyType" abstract="true" substitutionGroup="gml:_Object"/>
```

This abstract type supplies the root or base type for all topological elements including primitives and complexes. It inherits AbstractGMLType and hence can be identified using the gml:id attribute.

### 13.3.3 gml:AbstractTopoPrimitive, gml:\_TopoPrimitive

```
<complexType name="AbstractTopoPrimitiveType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractTopologyType">
      <sequence>
        <element ref="gml:isolated" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:container" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="_TopoPrimitive" type="gml:AbstractTopoPrimitiveType" abstract="true"
  substitutionGroup="gml:_Topology"/>
```

This abstract type acts as the base type for all topological primitive elements. Topology primitives are the atomic (smallest possible) units of a topology complex. Each topology primitive may contain references to other topology primitives of codimension 2 or more. So faces may isolate nodes and TopoSolids may isolate

nodes and edges. Conversely, nodes may have faces as containers and nodes and edges may have TopoSolids as containers.

### 13.3.4 gml:NodeType, gml:Node

```
<complexType name="NodeType">
  <complexContent>
    <extension base="gml:AbstractTopoPrimitiveType">
      <sequence>
        <element ref="gml:directedEdge" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:pointProperty" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Node" type="gml:NodeType" substitutionGroup="gml:_TopoPrimitive"/>
```

The Node type and global element represent the 0-dimensional primitive expressing point coincidence. The topological boundary of a node is empty and hence requires no representation. The optional coboundary of a node is a set of directed edges which are incident on this node.

NOTE In a 2D complex, this set may be ordered as a clockwise circular sequence. In a 3D complex, the order of this set is arbitrary.

Edges emanating from this node appear in the node coboundary with a negative orientation.

A node may optionally be realised by a 0-dimensional (point) geometric primitive.

### 13.3.5 gml:DirectedNodePropertyType, gml:directedNode

```
<complexType name="DirectedNodePropertyType">
  <choice>
    <element ref="gml:Node" minOccurs="0"/>
  </choice>
  <attribute name="orientation" type="gml:SignType" default="+"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="directedNode" type="gml:DirectedNodePropertyType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:directedNode">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>
```

The role of the DirectedNode type and element is in the boundary of topology edges and in the support of topological point features via the TopoPoint expression, see below. The orientation attribute of type gml:SignType expresses the sense in which the included node is used e.g. start (“-”) or end (“+”) node.

### 13.3.6 gml:EdgeType, gml:Edge

```
<complexType name="EdgeType">
  <complexContent>
    <extension base="gml:AbstractTopoPrimitiveType">
      <sequence>
        <element ref="gml:directedNode" minOccurs="2" maxOccurs="2"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

    <element ref="gml:directedFace" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="gml:curveProperty" minOccurs="0"/>
  </sequence>
</extension>
</complexContent>
</complexType>

<element name="Edge" type="gml:EdgeType" substitutionGroup="gml:_TopoPrimitive"/>

```

The Edge type and global element represent the 1-dimensional primitive expressing linear coincidence. The topological boundary of an Edge consists of a negatively directed start Node and a positively directed end Node. The optional coboundary of an edge is a circular sequence of directed faces which are incident on this edge in document order. Faces which use a particular boundary edge in its positive orientation appear with positive orientation on the coboundary of the same edge. In the 2D case, the orientation of the face on the left of the edge is "+"; the orientation of the face on the right on its right is "-". An edge may optionally be realised by a 1-dimensional (curve) geometric primitive.

### 13.3.7 gml:DirectedEdgePropertyType, gml:directedEdge

```

<complexType name="DirectedEdgePropertyType">
  <choice>
    <element ref="gml:Edge" minOccurs="0"/>
  </choice>
  <attribute name="orientation" type="gml:SignType" default="+"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="directedEdge" type="gml:DirectedEdgePropertyType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:directedEdge">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

```

The role of the DirectedEdge type and element is in the boundary of topology faces, in the coBoundary of topology nodes and in the support of topological line features via the TopoCurve expression, see below. The orientation attribute of type gml:SignType expresses the sense in which the included edge is used e.g. forward or reverse.

### 13.3.8 gml:FaceType, gml:Face

```

<complexType name="FaceType">
  <complexContent>
    <extension base="gml:AbstractTopoPrimitiveType">
      <sequence>
        <element ref="gml:directedEdge" maxOccurs="unbounded"/>
        <element ref="gml:directedTopoSolid" minOccurs="0" maxOccurs="2"/>
        <element ref="gml:surfaceProperty" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="Face" type="gml:FaceType" substitutionGroup="gml:_TopoPrimitive"/>

```

The Face type and global element represent the 2-dimensional topology primitive expressing surface overlap. The topological boundary of a face consists of a set of directed edges. Note that all edges associated with the face, including dangling edges, appear in the boundary. A dangling edge has the same face on both sides. Consequently, a dangling edge has two different nodes in its boundary. A dangling edge may share zero, one

or two bounding nodes with other edges in the boundary of a face. Two directedEdge elements with opposite orientations reference each dangling edge in the boundary of a face. The non-dangling edges in the boundary of a face comprise one or more topological rings. Each such ring consists of directedEdges connected in a cycle, and is oriented with the face on its left. The optional coboundary of a face is a pair of directed solids which are bounded by this face. If present, there is precisely one positively directed and one negatively directed solid in the coboundary of every face. The positively directed solid corresponds to the solid which lies in the direction of the negatively directed normal to the face in any geometric realisation. A face may optionally be realised by a 2-dimensional (surface) geometric primitive.

### 13.3.9 gml:DirectedFacePropertyType, gml:directedFace

```
<complexType name="DirectedFacePropertyType">
  <choice>
    <element ref="gml:Face" minOccurs="0"/>
  </choice>
  <attribute name="orientation" type="gml:SignType" default="+"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="directedFace" type="gml:DirectedFacePropertyType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:directedFace">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>
```

The role of the DirectedFace type and element is in the boundary of topology solids, in the coBoundary of topology edges and in the support of surface features via the TopoSurface expression, see below. The orientation attribute of type gml:SignType expresses the sense in which the included face is used e.g. inward or outward with respect to the surface normal in any geometric realisation.

### 13.3.10 gml:TopoSolidType, gml:TopoSolid

```
<complexType name="TopoSolidType">
  <complexContent>
    <extension base="gml:AbstractTopoPrimitiveType">
      <sequence>
        <element ref="gml:directedFace" maxOccurs="unbounded"/>
        <element ref="gml:solidProperty" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="TopoSolid" type="gml:TopoSolidType" substitutionGroup="gml:_TopoPrimitive"/>
```

The TopoSolid type and global element represent the 3-dimensional topology primitive expressing Volume interclause. The topological boundary of a TopoSolid consists of a set of directed faces. Note that all faces associated with the TopoSolid, including dangling faces, appear in the boundary. A dangling face has the same solid on both sides. Two directedFace elements with opposite orientations reference each dangling face in the boundary of a topological solid. The coboundary of a TopoSolid is empty and hence requires no representation. A TopoSolid may optionally be realised by a 2-dimensional (solid) geometric primitive.

### 13.3.11 gml:DirectedTopoSolidPropertyType, gml:directedTopoSolid

```
<complexType name="DirectedTopoSolidPropertyType">
```

```

<choice>
  <element ref="gml:TopoSolid"/>
</choice>
<attribute name="orientation" type="gml:SignType" default="+"/>
<attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="directedTopoSolid" type="gml:DirectedTopoSolidPropertyType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:directedTopoSolid">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

```

The role of the DirectedSolid type and element is in the coBoundary of topology faces and in the support of 3D volume features via the TopoVolume expression, see below. The orientation attribute of type gml:SignType expresses the sense in which the included solid appears in the face coboundary. Note that in the context of a TopoVolume the orientation attribute has no meaning in 3D.

### 13.3.12 gml:isolated

```

<element name="isolated" type="gml:IsolatedPropertyType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:isolated">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

<complexType name="IsolatedPropertyType">
  <choice minOccurs="0">
    <element ref="gml:Node"/>
    <element ref="gml:Edge"/>
  </choice>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

All of the adjacency relationships between topology primitives whose dimensions differ by +/- 1 are described using boundary and coboundary through directed topology primitive properties as described for each primitive. This includes instances where a dangling edge has the same face on both sides or a dangling face has the same solid on both sides. These primitives will appear twice in the boundary of the relevant face or solid with alternate sign. Primitives which are enclosed by another primitive of at least codimension 2 however, with no intermediate dimension primitive, are truly isolated. For faces this corresponds to nodes with no relationship to a bounding edge of the face. For solids, it corresponds to nodes or edges which are not referred to by the boundary faces of the solid.

Note a node may be isolated in a face and yet appear in the boundary of an edge which does *not* form part of the boundary of the face. In 3D this corresponds geometrically to a curve whose endpoint meets the interior of a surface.

### 13.3.13 gml:container

```

<element name="container" type="gml:ContainerPropertyType">
  <annotation>

```

```

<appinfo>
  <sch:pattern>
    <sch:rule context="gml:containerProperty">
      <sch:extends rule="hrefOrContent"/>
    </sch:rule>
  </sch:pattern>
</appinfo>
</annotation>
</element>

<complexType name="ContainerPropertyType">
  <choice minOccurs="0">
    <element ref="gml:Face"/>
    <element ref="gml:TopoSolid"/>
  </choice>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

The container type and element optionally contain the reciprocal relationships for the isolated property described above.

### 13.3.14 gml:TopoPointType, gml:TopoPoint

```

<complexType name="TopoPointType">
  <complexContent>
    <extension base="gml:AbstractTopologyType">
      <sequence>
        <element ref="gml:directedNode"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="TopoPoint" type="gml:TopoPointType"/>

```

The intended use of TopoPoint is to appear within a point feature to express the structural and possibly geometric relationships of this point to other features via shared node definitions. Note the orientation assigned to the directedNode has no meaning in this context. It is preserved for symmetry with the types and elements which follow.

### 13.3.15 gml:TopoPointPropertyType, gml:topoPointProperty

```

<complexType name="TopoPointPropertyType">
  <sequence>
    <element ref="gml:TopoPoint"/>
  </sequence>
</complexType>

<element name="topoPointProperty" type="gml:TopoPointPropertyType"/>

```

The topoPointProperty element can be used as a property of features to express their relationship to the referenced topology node.

### 13.3.16 gml:TopoCurveType, gml:TopoCurve

```

<complexType name="TopoCurveType">
  <complexContent>
    <extension base="gml:AbstractTopologyType">
      <sequence>
        <element ref="gml:directedEdge" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

```

    </complexContent>
  </complexType>

  <element name="TopoCurve" type="gml:TopoCurveType"/>

```

The TopoCurve type and element represent a homogeneous topological expression, a list of directed edges, which if realised are isomorphic to a geometric curve primitive. The intended use of TopoCurve is to appear within a line feature instance to express the structural and geometric relationships of this line to other features via the shared edge definitions.

### 13.3.17 gml:TopoCurvePropertyType, gml:topoCurveProperty

```

<complexType name="TopoCurvePropertyType">
  <sequence>
    <element ref="gml:TopoCurve"/>
  </sequence>
</complexType>

<element name="topoCurveProperty" type="gml:TopoCurvePropertyType"/>

```

The topoCurveProperty element can be used as a property of features to express their relationship to the referenced topology edges.

### 13.3.18 gml:TopoSurfaceType, gml:TopoSurface

```

<complexType name="TopoSurfaceType">
  <complexContent>
    <extension base="gml:AbstractTopologyType">
      <sequence>
        <element ref="gml:directedFace" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<element name="TopoSurface" type="gml:TopoSurfaceType"/>

```

The TopoSurface type and element represent a homogeneous topological expression, a set of directed faces, which if realised are isomorphic to a geometric surface primitive. The intended use of TopoSurface is to appear within a surface feature instance to express the structural and possibly geometric relationships of this surface to other features via the shared face definitions.

### 13.3.19 gml:TopoSurfacePropertyType, gml:topoSurfaceProperty

```

<complexType name="TopoSurfacePropertyType">
  <sequence>
    <element ref="gml:TopoSurface"/>
  </sequence>
</complexType>

<element name="topoSurfaceProperty" type="gml:TopoSurfacePropertyType"/>

```

The topoSurfaceProperty element can be used as a property of features to express their relationship to the referenced topology faces.

### 13.3.20 gml:TopoVolumeType, gml:TopoVolume

```

<complexType name="TopoVolumeType">
  <complexContent>
    <extension base="gml:AbstractTopologyType">
      <sequence>
        <element ref="gml:directedTopoSolid" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

```

    </sequence>
  </extension>
</complexContent>
</complexType>

<element name="TopoVolume" type="gml:TopoVolumeType"/>

```

The TopoVolume type and element represent a homogeneous topological expression, a set of directed TopoSolids, which if realised are isomorphic to a geometric solid primitive. The intended use of TopoVolume is to appear within a 3D solid feature instance to express the structural and geometric relationships of this solid to other features via the shared TopoSolid definitions. Note the orientation assigned to the directedSolid has no meaning in three dimensions. It is preserved for symmetry with the preceding types and elements.

### 13.3.21 gml:TopoVolumePropertyType, gml:topoVolumeProperty

```

<complexType name="TopoVolumePropertyType">
  <sequence>
    <element ref="gml:TopoVolume"/>
  </sequence>
</complexType>

<element name="topoVolumeProperty" type="gml:TopoVolumePropertyType"/>

```

The topoVolumeProperty element can be used as a property of features to express their relationship to the referenced topology Volume.

### 13.3.22 gml:TopoComplexType, gml:TopoComplex

A TopoComplex in GML is a collection of disconnected TopoPrimitives. If a topological primitive (other than a Node) is in a particular TopoComplex, then there exists a set of primitives of lower dimension in the same complex that form the boundary of this primitive.

```

<complexType name="TopoComplexType">
  <complexContent>
    <extension base="gml:AbstractTopologyType">
      <sequence>
        <element ref="gml:maximalComplex"/>
        <element ref="gml:superComplex" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:subComplex" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:topoPrimitiveMember" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:topoPrimitiveMembers" minOccurs="0"/>
      </sequence>
      <attribute name="isMaximal" type="boolean" default="false"/>
    </extension>
  </complexContent>
</complexType>

<element name="TopoComplex" type="gml:TopoComplexType" substitutionGroup="gml:_Topology"/>

```

This type and element provide encoding for a topology complex comprising multiple topology primitive members. In addition to primitives, each complex holds a reference to a unique maximal complex (the complex which has no supercomplex) and optionally to some number of sub- or super- complexes. A topology complex contains its primitive and sub-complex members, and is contained by its super-complex(es). The primitive and sub-complex members of a topological complex have dimensionality less than or equal to the dimensionality of the topology complex. There is one and only one maximal complex per topological manifold.

### 13.3.23 Maximal, sub- and super-complexes

```

<complexType name="TopoComplexMemberType">
  <sequence>
    <element ref="gml:TopoComplex" minOccurs="0"/>
  </sequence>
</complexType>

```

```

</sequence>
<attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="subComplex" type="gml:TopoComplexMemberType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:subComplex">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

<element name="superComplex" type="gml:TopoComplexMemberType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:superComplex">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

<element name="maximalComplex" type="gml:TopoComplexMemberType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:subComplex">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
    <documentation>Need schamatron test here that isMaximal attribute value is true</documentation>
  </annotation>
</element>

```

These elements and type provide encoding for relationships between topology complexes as described for the TopoComplexType.

#### 13.3.24 gml:topoPrimitiveMember

```

<element name="topoPrimitiveMember" type="gml:topoPrimitiveMemberType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:topoPrimitiveMember">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

<complexType name="topoPrimitiveMemberType">
  <sequence>
    <element ref="gml:_TopoPrimitive" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

This type and element encode the relationship between a topology complex and a single topology primitive.

### 13.3.25 gml:topoPrimitiveMembers

```
<element name="topoPrimitiveMembers" type="gml:TopoPrimitiveArrayAssociationType">
  <annotation>
    <appinfo>
      <sch:pattern>
        <sch:rule context="gml:topoPrimitiveMember">
          <sch:extends rule="hrefOrContent"/>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

<complexType name="TopoPrimitiveArrayAssociationType">
  <complexContent>
    <restriction base="gml:ArrayAssociationType">
      <sequence>
        <element ref="gml:_TopoPrimitive" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

This type and element encode the relationship between a topology complex and an arbitrary number of topology primitives. Note that because of the array style of encoding this type requires that the encodings for the topology primitives be in-line rather than remote properties.

### 13.3.26 gml:TopoComplexProperty, gml:topoComplexProperty

```
<complexType name="TopoComplexMemberType">
  <sequence>
    <element ref="gml:TopoComplex" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="topoComplexProperty" type="gml:TopoComplexMemberType"/>
```

This type and element encode the relationship between a GML object such as a feature collection and a topological complex. They allow a feature collection to contain or reference a topological complex that contains topologies referenced by members of the feature collection.

## 14 GML schemas – temporal information and dynamic features

### 14.1 Overview

The GML temporal schemas include components for describing temporal geometry and topology, temporal reference systems, and the temporal characteristics of geographic data. The model underlying the representation constitutes a profile of the conceptual schema described in ISO 19108:2002 [i]. The underlying spatiotemporal model strives to accommodate both feature-level and attribute-level time stamping; basic support for tracking moving objects is also included.

Time is measured on two types of scales: interval and ordinal. An interval scale offers a basis for measuring duration; an ordinal scale provides information only about relative position in time (e.g. a stratigraphic sequence or the geological time scale).

Two other ISO standards are relevant to describing temporal objects: ISO 8601 describes encodings for time instants and time periods, as text strings with particular structure and punctuation; ISO 11404 provides a detailed description of time intervals as part of a general discussion of language independent datatypes.

The temporal schemas cover two interrelated topics: three schema documents provide basic elements for representing temporal instants and periods, temporal topology, and reference systems; a more specialized schema document defines components used for dynamic features. Instances of temporal geometric types are used as values for the temporal properties of geographic features. All schemas are listed in Annex C.

## 14.2 Temporal schema

### 14.2.1 Overview

The basic temporal types and elements are described in the schema listed in Annex C. The main temporal schema is identified by the following location-independent name (using URN syntax):

#### 14.2.2 urn:opengis:specification:gml:schema-xsd:temporal:v3.1.0Temporal objects and properties

A hierarchy of elements is provided that matches the conceptual schema described in ISO 19108:2002. This includes a number of abstract (non-instantiable) elements at the top of the hierarchy.

##### 14.2.2.1 gml:\_TimeObject

The abstract element gml:\_TimeObject acts as the head of a substitution group for temporal primitives and complexes. It is declared in the schema as follows:

```
<element name="_TimeObject" type="gml:AbstractTimeObjectType" abstract="true" substitutionGroup="gml:_GML"/>
```

A gml:\_TimeObject may be used in any position that a gml:\_GML is valid. Its content model is defined as follows:

```
<complexType name="AbstractTimeObjectType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGMLType"/>
  </complexContent>
</complexType>
```

NOTE The content model of gml:\_TimeObject is a vacuous extension of AbstractGMLType. Types derived from this have the standard GML object properties available: metaDataProperty, description, name.

##### 14.2.2.2 gml:\_TimePrimitive

The abstract element TimePrimitive acts as the head of a substitution group for geometric and topological temporal primitives. It is declared in the schema as follows:

```
<element name="_TimePrimitive" type="gml:AbstractTimePrimitiveType" abstract="true"
substitutionGroup="gml:_TimeObject"/>
```

A gml:\_TimePrimitive may be used in any position that a gml:\_TimeObject is valid. Its content model is defined as follows:

```
<complexType name="AbstractTimePrimitiveType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractTimeObjectType">
      <sequence>
        <element name="relatedTime" type="gml:RelatedTimeType" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

This extends the model for generic temporal objects with properties indicating relationships between this temporal primitive and other temporal primitives. The definition of gml:RelatedTimeType is provided in subclause 14.2.2.4 below.

### 14.2.2.3 gml:TimePrimitivePropertyType, gml:validTime

gml:TimePrimitivePropertyType provides a standard content model for associations between an arbitrary member of the substitution group whose head is gml:\_TimePrimitive and another object:

```
<complexType name="TimePrimitivePropertyType">
  <sequence minOccurs="0">
    <element ref="gml:_TimePrimitive"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

gml:validTime is a convenience element declared as follows:

```
<element name="validTime" type="gml:TimePrimitivePropertyType"/>
```

### 14.2.2.4 gml:RelatedTimeType

gml:RelatedTimeType provides a content model for indicating the relative position of an arbitrary member of the substitution group whose head is gml:\_TimePrimitive. It extends the generic gml:TimePrimitivePropertyType with an XML attribute "relativePosition", whose value is selected from the set of 13 temporal relationships identified by Allen (1983) [ISO 19108:2002]:

```
<complexType name="RelatedTimeType">
  <complexContent>
    <extension base="gml:TimePrimitivePropertyType">
      <attribute name="relativePosition">
        <simpleType>
          <restriction base="string">
            <enumeration value="Before"/>
            <enumeration value="After"/>
            <enumeration value="Begins"/>
            <enumeration value="Ends"/>
            <enumeration value="During"/>
            <enumeration value="Equals"/>
            <enumeration value="Contains"/>
            <enumeration value="Overlaps"/>
            <enumeration value="Meets"/>
            <enumeration value="OverlappedBy"/>
            <enumeration value="MetBy"/>
            <enumeration value="BegunBy"/>
            <enumeration value="EndedBy"/>
          </restriction>
        </simpleType>
      </attribute>
    </extension>
  </complexContent>
</complexType>
```

### 14.2.2.5 gml:\_TimeComplex

A temporal complex shall be an aggregation of temporal primitives, represents a temporal geometric complex and a temporal topology complex. Temporal geometric complex is not defined in this clause. This standard does not distinguish a temporal linear graph from a temporal non-linear graph.

The abstract element `TimeComplex` acts as the head of a substitution group for temporal complexes. It is declared in the schema as follows:

```
<element name="_TimeComplex" type="gml:AbstractTimeComplexType" abstract="true"
substitutionGroup="gml:_TimeObject"/>
```

A `gml:_TimeComplex` may be used in any position that a `gml:_TimeObject` is valid. Its content model is defined as follows:

```
<complexType name="AbstractTimeComplexType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractTimeObjectType"/>
  </complexContent>
</complexType>
```

### 14.2.3 Temporal geometry

Temporal geometry is described in terms of time instants, periods, positions and lengths.

#### 14.2.3.1 gml:\_TimeGeometricPrimitive

The abstract element `TimeGeometricPrimitive` acts as the head of a substitution group for geometric temporal primitives. It is declared in the schema as follows:

```
<element name="_TimeGeometricPrimitive" type="gml:AbstractTimeGeometricPrimitiveType" abstract="true"
substitutionGroup="gml:_TimePrimitive"/>
```

A `gml:_TimeGeometricPrimitive` may be used in any position that a `gml:_TimePrimitive` is valid. Its content model is defined as follows:

```
<complexType name="AbstractTimeGeometricPrimitiveType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractTimePrimitiveType">
      <attribute name="frame" type="anyURI" use="optional" default="#ISO-8601"/>
    </extension>
  </complexContent>
</complexType>
```

A temporal geometry shall be associated with a temporal reference system through the **frame** attribute that provides a URI reference that identifies a description of the reference system. Following ISO 8601, the Gregorian calendar with UTC is the default reference system, but others may also be used. The GPS calendar and the Julian calendar are alternative reference systems in common use.

The two geometric primitives in the temporal dimension are the instant and the period. GML components are defined to support these as follows.

#### 14.2.3.2 gml:TimeInstant

An instant is a zero-dimensional geometric primitive that represents an identifiable position in time (it is equivalent to a point in space). In practice, an instant is an interval whose duration is less than a chronon—the resolution of the time scale..

The element `gml:TimeInstant` is declared as follows:

```
<element name="TimeInstant" type="gml:TimeInstantType" substitutionGroup="gml:_TimeGeometricPrimitive"/>
```

A `gml:TimeInstant` may be used in any position that a `gml:_TimeGeometricPrimitive` is valid. Its content model is defined as follows:

```
<complexType name="TimeInstantType" final="#all">
  <complexContent>
```

```

<extension base="gml:AbstractTimeGeometricPrimitiveType">
  <sequence>
    <element ref="gml:timePosition"/>
  </sequence>
</extension>
</complexContent>
</complexType>

```

In an instance document, a gml:TimeInstant contains a gml:timePosition as follows:

```

<gml:TimeInstant gml:id="t11">
  <gml:description>Abby's birthday</gml:description>
  <gml:timePosition>2001-05-23</gml:timePosition>
</gml:TimeInstant>

```

### 14.2.3.3 gml:TimeInstantPropertyType

gml:TimeInstantPropertyType is a specialisation of gml:TimePrimitivePropertyType that provides for associating a gml:TimeInstant with an object:

```

<complexType name="TimeInstantPropertyType">
  <sequence minOccurs="0">
    <element ref="gml:TimeInstant"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

### 14.2.3.4 gml:TimePeriod

A period is a one-dimensional geometric primitive that represents an identifiable extent in time (it is equivalent to a curve or envelope in space). It is an open interval bounded by beginning and end points (i.e. instants), and has length (i.e. duration). Its location in time is described by the temporal positions of the instants at which it begins and ends. The length of the period is equal to the temporal distance between the two bounding temporal positions.

The element **gml:TimePeriod** is declared as follows:

```

<element name="TimePeriod" type="gml:TimePeriodType" substitutionGroup="gml:_TimeGeometricPrimitive"/>

```

gml:TimePeriod may be used in any position that a gml:\_TimeGeometricPrimitive is valid. Its content model is defined as follows:

```

<complexType name="TimePeriodType">
  <complexContent>
    <extension base="gml:AbstractTimeGeometricPrimitiveType">
      <sequence>
        <choice>
          <element name="beginPosition" type="gml:TimePositionType"/>
          <element name="begin" type="gml:TimeInstantPropertyType"/>
        </choice>
        <choice>
          <element name="endPosition" type="gml:TimePositionType"/>
          <element name="end" type="gml:TimeInstantPropertyType"/>
        </choice>
        <element ref="gml:_timeLength" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

Both beginning and end may be described in terms of their direct position using `gml:TimePositionType` (clause 0) which is an XML Schema `simpleContent` type, or by reference to an identifiable time instant using `gml:TimeInstantPropertyType` (clause 14.2.3.3).

For example, within a `gml:TimePeriod`, a `gml:TimeInstant` may appear directly as the value of the begin and end as follows:

```
<gml:TimePeriod gml:id="p22">
  <gml:begin>
    <gml:TimeInstant gml:id="t11">
      <gml:timePosition>2001-05-23</gml:timePosition>
    </gml:TimeInstant>
  </gml:begin>
  <gml:end>
    <gml:TimeInstant gml:id="t12">
      <gml:timePosition>2001-06-23</gml:timePosition>
    </gml:TimeInstant>
  </gml:end>
</gml:TimePeriod>
```

Alternatively a limit of a `gml:timePeriod` may use the conventional GML property model to make a reference to a time instant described elsewhere, or a limit may be indicated as a direct position. The following mixed example shows both of these, as well as including the optional `gml:duration` property:

```
<gml:TimePeriod gml:id="p22">
  <gml:begin xlink:href="#t11"/>
  <gml:endPosition>2002-05-23</gml:endPosition>
  <gml:duration>P1Y</gml:duration>
</gml:TimePeriod>
```

#### 14.2.3.5 `gml:timePeriodPropertyType`

`gml:timePeriodPropertyType` is a specialisation of `gml:TimePrimitivePropertyType` that provides for associating a `gml:TimePeriod` with an object:

```
<complexType name="TimePeriodPropertyType">
  <sequence minOccurs="0">
    <element ref="gml:TimePeriod"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

#### 14.2.3.6 `gml:TimePositionType`, `gml:timePosition`

The method for identifying a temporal position is specific to each temporal reference system. `gml:timePositionType` supports the description of temporal position according to the subtypes described in ISO 19108:2002. Values based on calendars and clocks use lexical formats that are based on the ISO 8601 standard, as described in Part 2 of the XML Schema recommendation. A decimal value may be used with coordinate systems such as GPS time or UNIX time. A URI may be used to provide a reference to some era in an ordinal reference system (e.g. a geological epoch).

In common with many of the components using the stereotype `<<DataType>>` in the ISO 19100 specifications, the corresponding GML component has `simpleContent`. However, the content model `gml:TimePositionType` is defined in several steps:

```
<complexType name="TimePositionType" final="#all">
  <simpleContent>
    <extension base="gml:TimePositionUnion">
      <attribute name="frame" type="anyURI" use="optional" default="#ISO-8601"/>
      <attribute name="calendarEraName" type="string" use="optional"/>
      <attribute name="indeterminatePosition" type="gml:TimeIndeterminateValueType" use="optional"/>
    </extension>
  </simpleContent>
</complexType>
```

```
</simpleContent>
</complexType>
```

Three XML attributes appear on gml:TimePositionType:

A time value shall be associated with a temporal reference system through the **frame** attribute that provides a URI reference that identifies a description of the reference system. Following ISO 8601, the Gregorian calendar with UTC is the default reference system, but others may also be used. The GPS calendar and the Julian calendar are alternative reference systems in common use. Components for describing temporal reference systems are described in clause 14.3, but it is not required that the reference system be described in this, as the reference can refer to anything that may be identified with a URI.

For time values using a calendar containing more than one era, the (optional) **calendarEraName** attribute provides the name of the calendar era.

Inexact temporal positions may be expressed using the optional **indeterminatePosition** attribute. This takes a value from an enumeration defined as follows:

```
<simpleType name="TimeIndeterminateValueType">
  <restriction base="string">
    <enumeration value="after"/>
    <enumeration value="before"/>
    <enumeration value="now"/>
    <enumeration value="unknown"/>
  </restriction>
</simpleType>
```

These values are interpreted as follows:

- “unknown” indicates that no specific value for temporal position is provided.
- “now” indicates that the specified value shall be replaced with the current temporal position whenever the value is accessed.
- “before” indicates that the actual temporal position is unknown, but it is known to be before the specified value.
- “after” indicates that the actual temporal position is unknown, but it is known to be after the specified value.

A value for indeterminatePosition can be used either

- alone, or
- can qualify a specific value for temporal position (e.g. before 2002-12, after 1019624400).

The simpleType gml:TimePositionUnion is a union of XML Schema simple types which instantiate the subtypes for temporal position described in ISO 19108.

```
<simpleType name="TimePositionUnion">
  <union memberTypes="gml:CalDate time dateTime anyURI decimal"/>
</simpleType>
```

An ordinal era may be referenced via URI. A decimal value can be used to indicate the distance from the scale origin (e.g. UNIX time, GPS calendar). **time** is used for a position that recurs daily (see clause 5.4.4.2 of ISO 19108:2002).

Finally, calendar and clock forms that support the representation of time in systems based on years, months, days, hours, minutes and seconds, in a notation following ISO 8601, are assembled as follows:

```
<simpleType name="CalDate">
  <union memberTypes="date gYearMonth gYear"/>
</simpleType>
```

NOTE The XML Schema simpleType **dateTime** does not permit right-truncation, except for fractions of seconds, which is why **date**, **gYear** and **gYearMonth** are required.

NOTE Following ISO 19108:2002, when used with non-Gregorian calendars based on years, months, days, the same lexical representation should still be used. Following XML Schema part 2, leading zeros should be added if the year value would otherwise have fewer than four digits.

The element `gml:timePosition` is declared as follows:

```
<element name="timePosition" type="gml:TimePositionType"/>
```

This element is used directly as a property of `gml:TimeInstant` (see clause 14.2.3.2), and may also be used in application schemas. The following examples illustrate how `gml:timePosition` or other elements of this type may appear in a data instance:

```
<gml:timePosition>2002-11-25T13:20:20</gml:timePosition>
<gml:timePosition indeterminatePosition="after">1994</gml:timePosition>
<gml:timePosition indeterminatePosition="now"></gml:timePosition>
<gml:timePosition frame="http://my.big.org/TRS/GPS">25876321.01</gml:timePosition>
<gml:timePosition frame="http://my.big.org/TRS/archaeology"> http://my.history.org/eras/bronzeAge </gml:timePosition>
<gml:timePosition frame="http://my.big.org/TRS/calendars/japanese" calendarEraName="Meiji">0085-03</gml:timePosition>
```

#### 14.2.3.7 `gml:TimeLengthType`, `gml:_timeLength`, `gml:duration`, `gml:timeInterval`, `gml:TimeUnitType`

The length of a time period is described using the element `gml:_timeLength`, which is declared in the schema as follows:

```
<element name="_timeLength" type="gml:TimeDurationType" abstract="true">
```

`gml:_timeLength` is an abstract element, which acts as the head of a substitution group. Its content model is a union of the XML Schema duration and decimal simpleTypes, defined as follows:

```
<simpleType name="TimeLengthType">
  <union memberTypes="duration decimal"/>
</simpleType>
```

One member of the substitution group is `gml:duration`, which conforms to the ISO 8601 syntax for temporal length as implemented by the XML Schema duration type:

```
<element name="duration" type="duration" substitutionGroup="gml:_timeLength"/>
```

Another member of the substitution group is `gml:timeInterval` which conforms to the ISO 11404 standard which is based on floating point values for temporal length.

```
<element name="timeInterval" type="gml:TimeIntervalLengthType" substitutionGroup="gml:_timeLength"/>
```

```
<complexType name="TimeIntervalLengthType" final="#all">
  <simpleContent>
    <extension base="decimal">
      <attribute name="unit" type="gml:TimeUnitType" use="required"/>
      <attribute name="radix" type="positiveInteger" use="optional"/>
      <attribute name="factor" type="integer" use="optional"/>
    </extension>
  </simpleContent>
</complexType>
```

```

</extension>
</simpleContent>
</complexType>

```

ISO 11404 syntax specifies the use of a positiveInteger together with appropriate values for radix and factor. The resolution of the time interval is to one radix <sup>(-factor)</sup> of the specified time unit (e.g. unit="second", radix="10", factor="3" specifies a resolution of milliseconds).

The value of the unit is either selected from the units for time intervals from ISO 31-1:1992, or is another suitable unit. The encoding is defined for GML in gml:TimeUnitType:

```

<simpleType name="TimeUnitType">
  <union>
    <simpleType>
      <restriction base="string">
        <enumeration value="year"/>
        <enumeration value="month"/>
        <enumeration value="day"/>
        <enumeration value="hour"/>
        <enumeration value="minute"/>
        <enumeration value="second"/>
      </restriction>
    </simpleType>
    <simpleType>
      <restriction base="string">
        <pattern value="other:\w{2,}"/>
      </restriction>
    </simpleType>
  </union>
</simpleType>

```

The second component of this union type provides a method for indicating time units other than the six standard units given in the enumeration.

For example, to express a period length of 5 days, 14 hours, and 30 minutes any of the following instances are acceptable:

```

<duration>P5DT14H30M</duration>
<timeInterval unit="hour" radix="10" factor="0">134.5</timeInterval>
<timeInterval unit="other:week" radix="10" factor="0">0.800595</timeInterval>

```

## 14.3 Temporal topology schema

Temporal topology is described in terms of time complexes, nodes, and edges, and the connectivity between these. The temporal context of features that does not relate directly to position in time is described using connectivity relationships among instants and periods. These may incidentally provide information about the ordering of objects in time. Temporal topology does not directly provide information about temporal position. It is used in the case of describing a lineage or a history (ex. a family tree expressing evolution of species, an ecological cycle, a lineage of lands or buildings, or a history of separation and merger of administrative boundaries). This clause specifies the temporal topology as temporal characteristics of features in compliance with ISO 19108 – Temporal Schema.

### 14.3.1 Overview

The temporal topology types and elements are described in the schema listed in Annex C. The temporal topology schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:temporalTopology:v3.1.0
```

### 14.3.2 Temporal topology objects

A temporal topology object shall be a temporal element that describes the order of features or feature properties as temporal characteristics of features. The two temporal topology objects are primitive and complex. Annex C defines the schema for temporal topology objects.

As time is one dimensional topological space, temporal topology primitives shall be a time node corresponding to an instant, and a time edge corresponding to a period. A time node is an abstraction of an event that happened at a certain instant as a start or an end of more than one states. A state is a condition — a characteristic of a feature or data set that persists for a period. A “static feature” in this standard means a feature that holds the consistent identifier during its life span. Time edge is an abstraction of a state, and associates with time nodes representing its start and end. However, temporal topology primitives do not directly indicate “when” or “how long.” Time node may not be a start or an end of a time edge in the case of describing the event not associating with states. Such a node is called as an isolated node.

Topological complex is a collection of topological primitives that is closed under the boundary operation. A temporal topological complex shall be a connected acyclic directed graph composed of time edges and time nodes. A minimum temporal topological complex is a time edge with two time nodes at its both ends.

Example A lifecycle of a building can be described as a sequence of stages: plan, designing, construction, utilization, disposal and demolition. Each stage can be represented as a time edge. The boundary of each stage describing as a time node represents an event of decision-making, which terminates the stage and also originates the next stage. Thus, a lifecycle of a building is described as a temporal topology complex composed of a sequence of time edges connected with time nodes.

#### 14.3.2.1 gml:\_TimeTopologyPrimitive

Temporal topology primitives shall imply the ordering information between features or feature properties. The temporal connection of features can be examined, if they have temporal topology primitives as values of their properties. Usually, an instantaneous feature associates with a time node, and a static feature associates with a time edge. A feature with both modes associates with the temporal topology primitive: a supertype of time nodes and time edges.

The abstract element TimeTopologyPrimitive acts as the head of a substitution group for topological temporal primitives. It is defined in the schema as follows:

```
<element name="_TimeTopologyPrimitive" type="gml:AbstractTimeTopologyPrimitiveType" abstract="true"
substitutionGroup="gml:_TimePrimitive"/>
```

gml:\_TimeTopologyPrimitive may be used in any position that a gml:\_TimePrimitive is valid. Its content model is defined as follows:

```
<complexType name="AbstractTimeTopologyPrimitiveType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractTimePrimitiveType">
      <sequence>
        <element name="complex" type="gml:ReferenceType" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A topological primitive is always connected to one or more other topological primitives, and is, therefore, always a member of a topological complex. In a GML instance, this will often be indicated by the primitives being described by elements that are descendants of an element describing a complex. However, in order to support the case where a temporal topological primitive is described in another context, the optional “complex” property is provided, which carries a reference to the parent temporal topological complex.

### 14.3.2.2 gml:TimeTopologyPrimitivePropertyType

gml:TimeTopologyPrimitivePropertyType provides for associating a gml:\_TimeTopologyPrimitive with an object:

```
<complexType name="TimeTopologyPrimitivePropertyType">
  <sequence>
    <element ref="gml:_TimeTopologyPrimitive" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

### 14.3.2.3 gml:TimeTopologyComplex

Temporal topology complex shall be the connected acyclic directed graph composed of temporal topological primitives, i.e. time nodes and time edges. Because a time edge cannot exist without two time nodes on its boundaries, static features shall have time edges from temporal topology complex as the values of their temporal properties, regardless of explicit declarations.

Temporal topology complex expresses a linear or a non-linear graph. A temporal linear graph, composed of a sequence of time edges, provides a lineage described only by “substitution” of feature instances or feature element values. A time node as the start or the end of the graph connects with at least one time edge. A time node other than the start and the end shall connect to at least two time edges: one of starting from the node, and another ending at the node.

The element gml:TimeTopologyComplex is declared as follows:

```
<element name="TimeTopologyComplex" type="gml:TimeTopologyComplexType"
substitutionGroup="gml:_TimeComplex"/>
```

gml:TimeTopologyComplex may be used in any position that a gml:\_TimeComplex is valid. Its content model is defined as follows:

```
<complexType name="TimeTopologyComplexType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractTimeComplexType">
      <sequence>
        <element name="primitive" type="gml:TimeTopologyPrimitivePropertyType" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A temporal topological complex is a set of connected temporal topological primitives. The member primitives are indicated, either by reference or by value, using the “primitive” property.

### 14.3.2.4 gml:TimeNode

A time node is a zero-dimensional topological primitive that represents an identifiable node in time (it is equivalent to a point in space). A node may act as the termination or initiation of any number of time edges. A time node may be realised as a geometry, its position, whose value is a time instant.

The element gml:TimeNode is declared as follows:

```
<element name="TimeNode" type="gml:TimeNodeType" substitutionGroup="gml:_TimeTopologyPrimitive"/>
```

gml:TimeNode may be used in any position that a gml:\_TimeTopologyPrimitive is valid. Its content model is defined as follows:

```
<complexType name="TimeNodeType">
```

```

<complexContent>
  <extension base="gml:AbstractTimeTopologicalPrimitiveType">
    <sequence>
      <element name="previousEdge" type="gml:TimeEdgePropertyType" minOccurs="0" maxOccurs="unbounded"/>
      <element name="nextEdge" type="gml:TimeEdgePropertyType" minOccurs="0" maxOccurs="unbounded"/>
      <element name="position" type="gml:TimeInstantPropertyType" minOccurs="0"/>
    </sequence>
  </extension>
</complexContent>
</complexType>

```

#### 14.3.2.5 gml:TimeNodePropertyType

gml:TimeNodePropertyType provides for associating a gml:TimeNode with an object:

```

<complexType name="TimeNodePropertyType">
  <sequence>
    <element ref="gml:TimeNode" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

#### 14.3.2.6 gml:TimeEdge

A time edge is a one-dimensional topological primitive. It is an open interval that starts and ends at a node. The edge may be realised as a geometry whose value is a time period

The element gml:TimeEdge is declared as follows:

```

<element name="TimeEdge" type="gml:TimeEdgeType" substitutionGroup="gml:_TimeTopologyPrimitive"/>

```

gml:TimeEdge may be used in any position that a gml:\_ TimeTopologyPrimitive is valid. Its content model is defined as follows:

```

<complexType name="TimeEdgeType">
  <complexContent>
    <extension base="gml:AbstractTimeTopologyPrimitiveType">
      <sequence>
        <element name="start" type="gml:TimeNodePropertyType"/>
        <element name="end" type="gml:TimeNodePropertyType"/>
        <element name="extent" type="gml:TimePeriodPropertyType" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

#### 14.3.2.7 gml:TimeEdgePropertyType

gml:TimeEdgePropertyType provides for associating a gml:TimeEdge with an object:

```

<complexType name="TimeEdgePropertyType">
  <sequence>
    <element ref="gml:TimeEdge" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

#### 14.3.2.8 gml:SuccessionType

A temporal non-linear graph is a network composed of time edges. This provides a framework for describing successions of feature instances or feature property values described by “substitution”, “division” and “fusion”.

In support of application schemas that require this capability, the gml:SuccessionType is provided to ensure a consistent terminology. It is defined as follows:

```
<simpleType name="SuccessionType">
  <restriction base="string">
    <enumeration value="substitution"/>
    <enumeration value="division"/>
    <enumeration value="fusion"/>
    <enumeration value="initiation"/>
  </restriction>
</simpleType>
```

Note that successions may occur not only in the geographic data. For example, a restructuring of organization and an explication of philosophy are not always related to positions on the Earth, but frequently be accompanied with “division” or “fusion.”

## 14.4 Temporal reference systems

### 14.4.1 Overview

A value in the time domain is measured relative to a temporal reference system. Common types of reference systems include calendars, ordinal temporal reference systems, and temporal coordinate systems (time elapsed since some epoch, e.g. UNIX time, GPS time). The primary temporal reference system for use with geographic information is the Gregorian Calendar and 24 hour local or Coordinated Universal Time (UTC), but special applications may entail the use of alternative reference systems. The Julian day numbering system is a temporal coordinate system that has an origin earlier than any known calendar, at noon on 1 January 4713 BC in the Julian proleptic calendar, and is useful in transformations between dates in different calendars.

In GML seven concrete elements are used to describe temporal reference systems: TimeReferenceSystem, TimeCoordinateSystem, TimeCalendar, TimeCalendarEra, TimeClock, TimeOrdinalReferenceSystem, and TimeOrdinalEra.

The types and elements for temporal reference systems are described in the schema listed in Annex C. The schema is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:temporalReferenceSystems:v3.1.0
```

### 14.4.2 Basic temporal reference system

#### 14.4.2.1 gml:TimeReferenceSystem

A reference system is characterized in terms of its domain of validity: the spatial and temporal extent over which it is applicable. The basic GML element for temporal reference systems is gml:TimeReferenceSystem. Its content model simply extends gml:DefinitionType (see clause 15.2.1) with one property: domainOfValidity. In the schema this is implemented as follows:

```
<element name="TimeReferenceSystem" type="gml:TimeReferenceSystemType" substitutionGroup="gml:_GML"/>
```

gml:TimeReferenceSystem may be used in any position that a GML Object (gml:\_GML) is valid. Its content model is defined as follows:

```
<complexType name="TimeReferenceSystemType">
  <complexContent>
    <extension base="gml:DefinitionType">
      <sequence>
        <element name="domainOfValidity" type="string"/>
      </sequence>
    </extension>
  </complexContent>
```

```
</complexType>
```

The standard properties of a GML object are inherited from `gml:AbstractGMLType`. This element might appear in an instance document as follows:

```
<gml:TimeReferenceSystem gml:id="JulianCalendar">
  <gml:description xlink:href="http://aa.usno.navy.mil/data/docs/JulianDate.html"/>
  <gml:name>Julian Calendar</gml:name>
  <gml:domainOfValidity>Western Europe</gml:domainOfValidity>
</gml:TimeReferenceSystem>
```

### 14.4.3 Time Coordinate Systems

A temporal coordinate system shall be based on a continuous interval scale defined in terms of a single time interval.

#### 14.4.3.1 `gml:TimeCoordinateSystem`

The element `gml:TimeCoordinateSystem` is declared as follows:

```
<element name="TimeCoordinateSystem" type="gml:TimeCoordinateSystemType"
  substitutionGroup="gml:TimeReferenceSystem"/>
```

`gml:TimeCoordinateSystem` may be used in any position that a `gml:TimeReferenceSystem` is valid. Its content model is defined as follows:

```
<complexType name="TimeCoordinateSystemType">
  <complexContent>
    <extension base="gml:TimeReferenceSystemType">
      <sequence>
        <choice>
          <element name="originPosition" type="gml:TimePositionType"/>
          <element name="origin" type="gml:TimeInstantPropertyType"/>
        </choice>
        <element name="interval" type="gml:TimeIntervalLengthType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The model follows `TM_CoordinateSystem` from ISO 19108, except in the following details:

- the origin is specified either using the property `gml:originPosition` whose value is a direct time position (clause 14.2.3.6), or using the property `gml:origin` whose model is `gml:TimeInstantPropertyType` (clause 14.2.3.3): this permits more flexibility in representation and also supports referring to a value fixed elsewhere
- the interval uses `gml:TimeIntervalLengthType`, defined in clause 14.2.3.7.

Coordinate systems might be described in data instances as follows:

```
<gml:TimeCoordinateSystem gml:id="Laser36">
  <gml:description>Time scale used during a laser experiment</gml:description>
  <gml:name>Laser timescale 36</gml:name>
  <gml:domainOfValidity>Laser laboratory</gml:domainOfValidity>
  <gml:origin>
    <gml:TimeInstant>
      <gml:timePosition>2002-11-28T12:50:00+08:00</gml:timePosition>
    </gml:TimeInstant>
  </gml:origin>
  <gml:interval unit="second" radix="10" factor="12">1.0</gml:interval>
</gml:TimeCoordinateSystem>
```

```

<gml:TimeCoordinateSystem gml:id="geologyMa">
  <gml:name>Geological time system</gml:name>
  <gml:domainOfValidity>Earth</gml:domainOfValidity>
  <gml:origin>
    <gml:TimeInstant>
      <gml:description xlink:href="http://www.c14dating.com/agecalc.html">Conventional origin used for carbon dating.
      Equivalent to "present" for other radiometric dating techniques which have much lower precision.</gml:description>
      <gml:timePosition>1950</gml:timePosition>
    </gml:TimeInstant>
  </gml:origin>
  <gml:interval unit="year" radix="10" factor="-6">1.0</gml:interval>
</gml:TimeCoordinateSystem>

```

#### 14.4.4 Calendars and clocks

Calendars and clocks are both based on interval scales. A calendar is a discrete temporal reference system that provides a basis for defining temporal position to a resolution of one day. A clock provides a basis for defining temporal position within a day. A clock must be used with a calendar in order to provide a complete description of a temporal position within a specific day.

Calendars have a variety of complex internal structures. This schema defines a simple external calendar interface. Every calendar provides a set of rules for composing a calendar date from a set of elements such as year, month, and day. In every calendar, years are numbered relative to the date of a reference event that defines a calendar era. A single calendar may reference more than one calendar era

##### 14.4.4.1 gml:TimeCalendar, gml:TimeCalendarEra

A calendar is a discrete temporal reference system that provides a basis for defining temporal position to a resolution of one day. The element gml:TimeCalendar is declared as follows:

```
<element name="TimeCalendar" type="gml:TimeCalendarType" substitutionGroup="gml:TimeReferenceSystem"/>
```

gml:TimeCalendarEra may be used in any position that a gml:TimeReferenceSystem is valid. Its content model is defined as follows:

```

<complexType name="TimeCalendarType">
  <complexContent>
    <extension base="gml:TimeReferenceSystemType">
      <sequence>
        <element name="referenceFrame" type="gml:TimeCalendarEraPropertyType" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

gml:TimeCalendar adds one property to those inherited from gml:TimeReferenceSystem:

referenceFrame: link to a Calendar Era that it uses;

A gml:TimeCalendar may reference more than one Calendar Era. The referenceFrame element follows the standard GML property model, allowing the association to be instantiated either using an inline description using the gml:TimeCalendarEra element, or a link to a description of the Calendar Era which is explicit elsewhere. The gml:TimeCalendarEra element is declared as follows

```
<element name="TimeCalendarEra" type="gml:TimeCalendarEraType" />
```

Its content model is defined as follows:

```

<complexType name="TimeCalendarEraType">
  <complexContent>
    <extension base="gml:DefinitionType">

```

```

<sequence>
  <element name="referenceEvent" type="gml:StringOrRefType"/>
  <element name="referenceDate" type="gml:CalDate"/>
  <element name="julianReference" type="decimal"/>
  <element name="epochOfUse" type="gml:TimePeriodPropertyType"/>
</sequence>
</extension>
</complexContent>
</complexType>

```

`gml:TimeCalendarEra` inherits basic properties from `gml:DefinitionType` (clause 15.2.1), has the following properties:

`referenceEvent`: Name or description of a mythical or historic event which fixes the position of the base scale of the calendar era. This is given as text or using a link to description held elsewhere

`referenceDate`: Date of the `referenceEvent` expressed as a date in the given calendar. In most calendars, this date is the origin (i.e., the first day) of the scale, but this is not always true

`julianReference`: Julian date that corresponds to the reference date. The Julian day number is an integer value; the Julian date is a decimal value that allows greater resolution. Transforming calendar dates to and from Julian dates provides a relatively simple basis for transforming dates from one calendar to another

`epochOfUse`: Period for which the calendar era was used as a basis for dating.

#### 14.4.4.2 `gml:TimeClock`

A clock provides a basis for defining temporal position within a day. A clock must be used with a calendar in order to provide a complete description of a temporal position within a specific day. The element `gml:TimeClock` is declared as follows:

```
<element name="TimeClock" type="gml:TimeClockType" substitutionGroup="gml:TimeReferenceSystem"/>
```

`gml:TimeClock` may be used in any position that a `gml:TimeReferenceSystem` is valid. Its content model is defined as follows:

```

<complexType name="TimeClockType" final="#all">
  <complexContent>
    <extension base="gml:TimeReferenceSystemType">
      <sequence>
        <element name="referenceEvent" type="gml:StringOrRefType"/>
        <element name="referenceTime" type="time"/>
        <element name="utcReference" type="time"/>
        <element name="dateBasis" type="gml:TimeCalendarPropertyType" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

`gml:TimeClock` adds the following properties to those inherited from generic `gml:TimeReferenceSystemType`:

`referenceEvent`: Name or description of an event, such as solar noon or sunrise, which fixes the position of the base scale of the clock

`referenceTime`: time of day associated with the reference event expressed as a time of day in the given clock. The reference time is usually the origin of the clock scale.

`UtcReference`: 24 hour local or UTC time that corresponds to the reference time.

`DateBasis`: pointer to the calendars that use this clock.

#### 14.4.5 Time Ordinal Reference Systems

In some applications of geographic information — such as geology and archaeology — relative position in time is known more precisely than absolute time or duration. The order of events in time can be well established, but the magnitude of the intervals between them cannot be accurately determined; in such cases, the use of an ordinal temporal reference system is appropriate. An ordinal temporal reference system is composed of a sequence of named coterminous eras, which may in turn be composed of sequences of member eras at a finer scale, giving the whole a hierarchical structure of eras of varying resolution.

An ordinal temporal reference system whose component eras are not further subdivided is effectively a temporal topological complex constrained to be a linear graph. An ordinal temporal reference system some or all of whose component eras are subdivided is effectively a temporal topological complex with the constraint that parallel branches may only be constructed in pairs where one is a single temporal ordinal era and the other is a sequence of temporal ordinal eras that are called "members" of the "group". This constraint means that within a single temporal ordinal reference system, the relative position of all temporal ordinal eras is unambiguous.

The positions of the beginning and end of a given era may calibrate the relative time scale.

##### 14.4.5.1 gml:TimeOrdinalReferenceSystem, gml:TimeOrdinalEra

The element gml:TimeOrdinalReferenceSystem implements this by adding a set of gml:component properties to the generic temporal reference system model. It is declared as follows:

```
<element name="TimeOrdinalReferenceSystem" type="gml:TimeOrdinalReferenceSystemType"
substitutionGroup="gml:TimeReferenceSystem"/>
```

gml:TimeOrdinalReferenceSystem may be used in any position that a gml:TimeReferenceSystem is valid. Its content model is defined as follows:

```
<complexType name="TimeOrdinalReferenceSystemType">
  <complexContent>
    <extension base="gml:TimeReferenceSystemType">
      <sequence>
        <element name="component" type="gml:TimeOrdinalEraPropertyType" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The content model for gml:TimeOrdinalEra follows the pattern of gml:TimeEdge (clause 14.3.2.6), inheriting standard properties from gml:DefinitionType (clause 15.2.1), and adding gml:start, gml:end and gml:extent properties, a set of gml:member properties which indicate ordered gml:TimeOrdinalEra elements, and a gml:group property which points to the parent era. This is implemented as follows:

```
<element name="TimeOrdinalEra" type="gml:TimeOrdinalEraType"/>
<complexType name="TimeOrdinalEraType">
  <complexContent>
    <extension base="gml:DefinitionType">
      <sequence>
        <element name="relatedTime" type="gml:RelatedTimeType" minOccurs="0" maxOccurs="unbounded"/>
        <element name="start" type="gml:TimeNodePropertyType"/>
        <element name="end" type="gml:TimeNodePropertyType"/>
        <element name="extent" type="gml:TimePeriodPropertyType" minOccurs="0"/>
        <element name="member" type="gml:TimeOrdinalEraPropertyType" minOccurs="0" maxOccurs="unbounded"/>
        <element name="group" type="gml:ReferenceType" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The model for the component and member properties follows the normal GML property pattern:

```
<complexType name="TimeOrdinalEraPropertyType">
  <sequence minOccurs="0">
    <element ref="gml:TimeOrdinalEra"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

The recursive inclusion of gml:TimeOrdinalEra elements allow the construction of an arbitrary depth hierarchical ordinal reference schema, such that an ordinal era at a given level of the hierarchy includes a sequence of shorter, coterminous ordinal eras.

The example below shows a portion of the geological time scale depicted as an ordinal reference system:

```
<gml:TimeOrdinalReferenceSystem gml:id="GeologicalTimeScale">
  <gml:description xlink:href="ftp://ftp.iugs.org/pub/iugs/iugs_intstratchart.pdf"/>
  <gml:name>Geological time scale</gml:name>
  <gml:domainOfValidity>Earth</gml:domainOfValidity>
  <!-- Earlier eras omitted -->
  <gml:component>
    <gml:TimeOrdinalEra gml:id="Cenozoic">
      <gml:name>Cenozoic Era</gml:name>
      <gml:start xlink:href="#basePaleocene"/>
      <gml:end xlink:href="#now"/>
      <gml:member>
        <gml:TimeOrdinalEra gml:id="Tertiary">
          <gml:name>Tertiary Period</gml:name>
          <gml:start xlink:href="#baseTertiary"/>
          <gml:end xlink:href="#basePleistocene"/>
          <gml:member>
            <gml:TimeOrdinalEra gml:id="Paleogene">
              <gml:name>Paleogene sub-period</gml:name>
              <gml:start>
                <gml:TimeInstant gml:id="basePaleogene">
                  <gml:timePosition frame="#geologyMa">65.0</gml:timePosition>
                </gml:TimeInstant>
              </gml:start>
              <gml:end xlink:href="#baseNeogene"/>
              <gml:member>
                <gml:TimeOrdinalEra gml:id="Paleocene">
                  <gml:name>Paleocene Epoch</gml:name>
                  <gml:start xlink:href="#basePaleogene"/>
                  <gml:end xlink:href="#baseEocene"/>
                </gml:TimeOrdinalEra>
              </gml:member>
              <gml:member>
                <gml:TimeOrdinalEra gml:id="Eocene">
                  <gml:name>Paleocene Epoch</gml:name>
                  <gml:start>
                    <gml:TimeInstant gml:id="baseEocene">
                      <gml:timePosition frame="#geologyMa">57.8</gml:timePosition>
                    </gml:TimeInstant>
                  </gml:start>
                  <gml:end xlink:href="#baseOligocene"/>
                </gml:TimeOrdinalEra>
              </gml:member>
              <gml:member>
                <gml:TimeOrdinalEra gml:id="Oligocene">
                  <gml:name>Oligocene Epoch</gml:name>
                  <gml:start>
                    <gml:TimeInstant gml:id="baseOligocene">
                      <gml:timePosition frame="#geologyMa">33.7</gml:timePosition>
                    </gml:TimeInstant>
                  </gml:start>
                </gml:TimeOrdinalEra>
              </gml:member>
            </gml:member>
          </gml:member>
        </gml:member>
      </gml:member>
    </gml:TimeOrdinalEra>
  </gml:component>
</gml:TimeOrdinalReferenceSystem>
```

```

</gml:start >
<gml:end xlink:href="#baseNeogene"/>
</gml:TimeOrdinalEra>
</gml:member>
</gml:TimeOrdinalEra>
</gml:member>
<!-- Neogene sub-period and Quaternary period omitted -->
</gml:TimeOrdinalEra>
</gml:member>
</gml:TimeOrdinalEra>
</gml:component>
</gml:TimeOrdinalReferenceSystem>

```

Note that the use of references on various begin and end elements allows the position of the boundaries between eras to be recorded once and then re-used many times as appropriate, corresponding to a non-linear graph when appropriate. All positions refer to a frame “geologyMa” which would be defined as a temporal coordinate system (e.g see clause 14.4.3).

## 14.5 Representing dynamic features

### 14.5.1 Overview

A number of types and relationships are defined to represent the time-varying properties of geographic features. The dynamic feature schema is listed in Annex C; it is identified by the following location-independent name (using URN syntax):

urn:opengis:specification:gml:schema-xsd:dynamicFeature:v3.1.0

In a comprehensive treatment of spatiotemporal modeling, Langran [see bibliography] distinguished three principal temporal entities: *states*, *events*, and *evidence*; this schema incorporates elements for each. A simple UML model for dynamic features is shown in Figure.

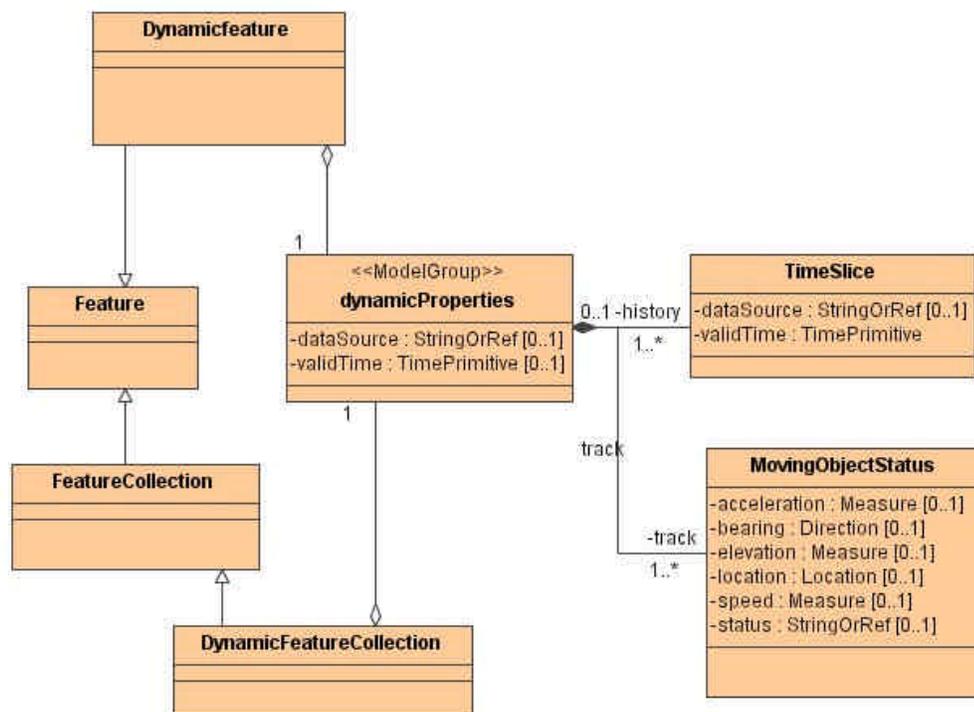

Figure 3 – Dynamic Features

### 14.5.2 gml:dataSource

In GML, *evidence* is represented by a simple **dataSource** property that indicates the source of the temporal data (e.g. human observer, *in situ* sensor).

```
<element name="dataSource" type="gml:StringOrRefType" abstract="true"/>
```

### 14.5.3 Dynamic Properties

A convenience group gml:dynamicProperties is defined in the schema as follows:

```
<group name="dynamicProperties">
  <sequence>
    <element ref="gml:validTime" minOccurs="0"/>
    <element ref="gml:history" minOccurs="0"/>
    <element ref="gml:dataSource" minOccurs="0"/>
  </sequence>
</group>
```

This allows an application schema developer to include dynamic properties in a content model in a standard fashion. The gml:validTime property is declared in temporal.xsd (described in clause 14.2.2.3 above). The other properties are declared elsewhere in this clause.

### 14.5.4 Dynamic Features

*States* are captured by time-stamped instances of a feature or feature collection. The content model for a dynamic feature extends the standard AbstractFeatureType and FeatureCollectionType with the gml:dynamicProperties model group defined above:

```
<complexType name="DynamicFeatureType">
  <complexContent>
    <extension base="gml:AbstractFeatureType">
      <group ref="gml:dynamicProperties"/>
    </extension>
  </complexContent>
</complexType>

<complexType name="DynamicFeatureCollectionType">
  <complexContent>
    <extension base="gml:FeatureCollectionType">
      <group ref="gml:dynamicProperties"/>
    </extension>
  </complexContent>
</complexType>
```

Each time-stamped instance represents a ‘snapshot’ of a feature. The dynamic feature classes will normally be extended to suit particular applications. A dynamic feature bears either a time stamp or a history.

NOTE A history consists of a set of gml:TimeSlices and such time slices can contain any time varying properties. We might for example use such a mechanism to describe a feature with one property that varies in time.

### 14.5.5 gml:DynamicFeatureCollection

A DynamicFeatureCollection is a FeatureCollection that has a validTime property (i.e. is a snapshot of the FeatureCollection) or which has a gml:history property that contains one or more gml:TimeSlices each of which contain values of the time varying properties of the FeatureCollection. Note that the DynamicFeatureCollection can be one of the following:

1. A FeatureCollection which consists of static feature members (members do not change in time) but which has properties of the collection object as a whole that do change in time (e.g. described by a history). An example might be a Train. The Train is a gml:FeatureCollection. The position and speed of the train are time varying and could be captured in the history of the Train. The featureMembers of the Train are the individual cars including the locomotive. The properties of the cars are static such as the position of the car in the train (we ignore any re-organization of the train in this example), the cargo, the make of the car and its type (e.g. grain car, oil car etc.).
2. A FeatureCollection which consists of dynamic feature members (the members are DynamicFeatures) but which also has properties of the collection as a whole that vary in time. An example could be a collection of sail boats in a yachting race. The sail boats may disappear from the race or reappear. The area encompassing the boats in the race (think of a race like the Vendée Globe would be time variant).

NOTE One can also have a FeatureCollection with dynamic feature members but such that the properties of the collection as a whole are static. This might also be applied to the sail boat race where we only have properties like the organization committee, and the location of the starting point and finish line.

#### 14.5.6 gml:\_TimeSlice

To describe an *event* — an action that occurs at an instant or over an interval of time — GML provides the abstract **TimeSlice** element, which is declared in the schema as follows:

```
<element name="_TimeSlice" type="gml:AbstractTimeSliceType" abstract="true" substitutionGroup="gml:_GML"/>
<complexType name="AbstractTimeSliceType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGMLType">
      <sequence>
        <element ref="gml:validTime"/>
        <element ref="gml:dataSource" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A timeslice encapsulates the time-varying properties of a dynamic feature -- it must be extended to represent a time stamped projection of a specific feature. The `dataSource` property describes how the temporal data was acquired.

A `TimeSlice` instance is a GML object that encapsulates updates of the dynamic—or volatile—properties that reflect some change event; it thus includes only those feature properties that have actually changed due to some process. For example, suppose that ownership of a building changes and it is renamed. If no other building properties have changed, then the event will only include the updated name. The `TimeSlice` class basically provides a facility for *attribute-level* time stamping, in contrast to the *object-level* time stamping of dynamic feature instances.

The time slice can thus be viewed as event or process-oriented, whereas a snapshot is more state or structure-oriented. A timeslice has richer causality, whereas a snapshot merely portrays the status of the whole. For example, a feature collection might have a 'life cycle' represented by a sequence of snapshots (Figure Figure 14.4.6-2).

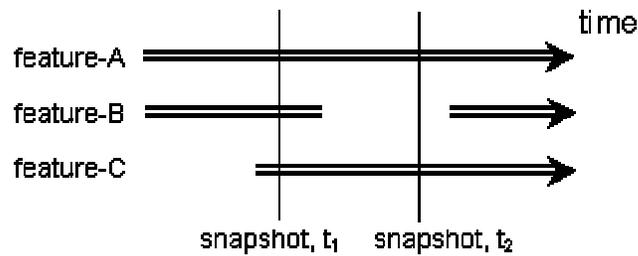

Figure 14.4.6-2— The life cycle of a feature collection

At instant  $t_1$ , feature-A, feature-B, and feature-C are all members of the collection. However, at instant  $t_2$  only feature-A and feature-B are members. Closer examination of the history of feature-B will reveal its ephemeral nature (e.g. a building is dismantled and reconstructed on a seasonal basis).

#### 14.5.7 gml:MovingObjectStatus

The `gml:MovingObjectStatus` element is one example of how the `gml:TimeSlice` may be extended. This element provides a standard method to capture a record of the status of a moving object. It is declared as follows:

```
<element name="MovingObjectStatus" type="gml:MovingObjectStatusType" substitutionGroup="gml:TimeSlice"/>

<complexType name="MovingObjectStatusType">
  <complexContent>
    <extension base="gml:AbstractTimeSliceType">
      <sequence>
        <element ref="gml:position"/>
        <element name="speed" type="gml:MeasureType" minOccurs="0"/>
        <element name="bearing" type="gml:DirectionPropertyType" minOccurs="0"/>
        <element name="acceleration" type="gml:MeasureType" minOccurs="0"/>
        <element name="elevation" type="gml:MeasureType" minOccurs="0"/>
        <element ref="gml:status" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

A `gml:MovingObjectStatus` element allows the user to describe the present location, along with the speed, bearing, acceleration and elevation of an object in a particular time slice.

Additional information about the current status of the object can be recorded in the `gml:status` element, declared as follows:

```
<element name="status" type="gml:StringOrRefType"/>
```

#### 14.5.8 gml:history

A generic sequence of events constitute a **history** of an object. This GML property element is declared in the schema as follows:

```
<element name="history" type="gml:HistoryPropertyType"/>

<complexType name="HistoryPropertyType">
  <sequence>
    <element ref="gml:_TimeSlice" maxOccurs="unbounded"/>
  </sequence>
</complexType>
```

The gml:history element contains a set of elements in the substitution group headed by the abstract element gml:\_TimeSlice, representing the time-varying properties of interest. The history property of a dynamic feature associates a feature instance with a sequence of time slices (i.e. change events) that encapsulate the evolution of the feature.

### 14.5.9 gml:track

A track is a specific kind of history. The gml:track element is declared in the schema as follows:

```
<element name="track" type="gml:TrackType" substitutionGroup="gml:history"/>

<complexType name="TrackType">
  <complexContent>
    <restriction base="gml:HistoryPropertyType">
      <sequence>
        <element ref="gml:MovingObjectStatus" maxOccurs="unbounded"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

If the feature represents a moving object such as a ground vehicle or a ship, then the **track** property comprises a sequence of MovingObjectStatus elements. For example, a dynamic feature such as a cyclone may have a gml:track property such as shown in the following fragment:

```
<gml:track>
  <gml:MovingObjectStatus>
    <gml:validTime><gml:TimeInstant>
      <gml:timePosition>2005-11-28T13:00:00</gml:timePosition>
    </gml:TimeInstant></gml:validTime>
    <gml:location><gml:Point>
      <gml:pos>140. -35.</gml:pos>
    </gml:Point></gml:location>
    <gml:speed uom="#kph">12.</gml:speed>
    <gml:bearing>
      <gml:CompassPoint>SE</gml:CompassPoint>
    </gml:bearing>
  </gml:MovingObjectStatus>
  <gml:MovingObjectStatus>
    <gml:validTime><gml:TimeInstant>
      <gml:timePosition>2005-11-28T14:00:00</gml:timePosition>
    </gml:TimeInstant></gml:validTime>
    <gml:location><gml:Point>
      <gml:pos>140.1 -34.9</gml:pos>
    </gml:Point></gml:location>
    <gml:speed uom="#kph">23.</gml:speed>
    <gml:bearing>
      <gml:CompassPoint>ESE</gml:CompassPoint>
    </gml:bearing>
  </gml:MovingObjectStatus>
</gml:track>
```

## 15 GML schemas – definitions and dictionaries

### 15.1 Overview

Many applications require definitions of terms, which are used within instance documents as the values of certain properties or as reference information to tie properties to standard information values in some way. Units of measure, and descriptions of measurable phenomena, are two particular examples.

It will often be convenient to use definitions provided by external authorities. These may already be packaged for delivery in various ways, both online and offline. In order that they may be referred to from GML documents it is generally necessary that a URI be available for each definition. Where this is the case then it is usually preferable to refer to these directly.

Alternatively, it may be convenient or necessary to capture definitions in XML, either embedded within an instance document containing Features or as a separate document. The definitions may be transcriptions from an external source, or may be new definitions for a local purpose. In order to support this case, some simple components are provided in GML in the form of

- a) a generic Definition, which may serve as the basis for more specialized definitions
- b) a generic Dictionary, also known as DefinitionCollection, which allows a set of definitions or references to definitions to be collected

These components may be used directly, but also serve as the basis for more specialised definition elements in GML, in particular: coordinate operations (clause 12), coordinate reference systems (clause 12), datums (clause 12), temporal reference systems (clause 14), units of measure (clause 16).

Note that the GML definition and dictionary components implement a simple nested hierarchy of definitions with identifiers. The latter provide handles which may be used in the description of more complex relationships between terms. However, the GML dictionary components are not intended to provide direct support for complex taxonomies, ontologies or thesauri. Specialised XML tools are available to satisfy the more sophisticated requirements.

## 15.2 Dictionary schema

The dictionary schema is listed in Annex C; it is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:dictionary:v3.1.0
```

### 15.2.1 gml:Definition, gml:DefinitionType

The basic Definition element is declared in the schema as follows:

```
<element name="Definition" type="gml:DefinitionType" substitutionGroup="gml:_GML"/>
<complexType name="DefinitionType">
  <complexContent>
    <restriction base="gml:AbstractGMLType">
      <sequence>
        <element ref="gml:metaDataProperty" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:description" minOccurs="0"/>
        <element ref="gml:name" minOccurs="1" maxOccurs="unbounded"/>
      </sequence>
      <attribute ref="gml:id" use="required"/>
    </restriction>
  </complexContent>
</complexType>
```

The content model for a generic definition is a simple derivation from AbstractGMLType. Since it is necessary to be able to refer to a definition, the gml:id attribute which provides the database handle for a GML object is mandatory. The "description" element shall hold the definition if this can be captured in a simple text string, or may carry a link to a description elsewhere. The "name" elements shall provide one or more terms and synonyms for which this is the definition. The "metaDataProperty" elements may be used to reference or include more information about this definition.

## 15.2.2 gml:Dictionary, gml:DefinitionCollection, gml:DictionaryType

Sets of definitions may be collected into dictionaries or collections. These are declared in the schema as follows:

```
<element name="Dictionary" type="gml:DictionaryType" substitutionGroup="gml:Definition"/>
<element name="DefinitionCollection" type="gml:DictionaryType" substitutionGroup="gml:Definition"/>
<complexType name="DictionaryType">
  <complexContent>
    <extension base="gml:DefinitionType">
      <choice minOccurs="0" maxOccurs="unbounded">
        <element ref="gml:dictionaryEntry"/>
        <element ref="gml:indirectEntry"/>
      </choice>
    </extension>
  </complexContent>
</complexType>
```

A Dictionary is a non-abstract collection of definitions. These definitions are referenced from other places, in the same and different XML documents.

The Dictionary content model adds a list of dictionaryEntry and indirectEntry properties that contain or reference Definition objects. A database handle (gml:id attribute) is required, in order that this collection may be referred to. The standard metaDataProperty, description and name are available to reference or contain more information about this dictionary. The inherited "description" element can be used for a description of this dictionary. The inherited "name" element can be used for the name(s) of this dictionary.

## 15.2.3 gml:dictionaryEntry, gml:definitionMember, gml:DictionaryEntryType

These elements contain or refer to the definitions which are members of this dictionary. The element gml:dictionaryEntry is declared as follows:

```
<element name="dictionaryEntry" type="gml:DictionaryEntryType"/>
<element name="definitionMember" type="gml:DictionaryEntryType" substitutionGroup="gml:dictionaryEntry"/>
<complexType name="DictionaryEntryType">
  <sequence>
    <element ref="gml:Definition" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

The content model follows the standard GML property pattern, so a gml:dictionaryEntry may either contain or refer to a single gml:Definition. Since gml:Dictionary is substitutable for gml:Definition, the content of an entry can itself be a lower level dictionary or definition collection.

Note that if the value is provided by reference, this definition does *not* carry a handle (gml:id) in this context, so does *not* allow external references to this specific definition in this context. When used in this way the referenced definition will usually be in a dictionary in the same XML document.

## 15.2.4 gml:indirectEntry, gml:IndirectEntryType, gml:DefinitionProxy, gml:DefinitionProxyType

If a definition shall be included by reference, in its context within the current collection, then gml:indirectEntry shall be used. This is declared as follows:

```
<element name="indirectEntry" type="gml:IndirectEntryType"/>
<complexType name="IndirectEntryType">
```

```

<sequence>
  <element ref="gml:DefinitionProxy"/>
</sequence>
</complexType>

```

A gml:indirectEntry contains a proxy object gml:DefinitionProxy which is declared as follows:

```

<element name="DefinitionProxy" type="gml:DefinitionProxyType" substitutionGroup="gml:Definition"/>

<complexType name="DefinitionProxyType">
  <complexContent>
    <extension base="gml:DefinitionType">
      <sequence>
        <element ref="gml:definitionRef"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

A gml:DefinitionProxy carries a mandatory handle (gml:id), and contains a reference to a definition represented elsewhere. This entry is expected to be convenient in allowing multiple elements in one XML document to contain short (abbreviated XPointer) references, which are resolved to an external definition provided in a Dictionary element in the same XML document.

The reference is carried by a gml:definitionRef element which is declared as follows.

```

<element name="definitionRef" type="gml:ReferenceType"/>

```

This uses the gml:ReferenceType which is described in clause 7.5.3.2. The remote entry referenced can be in a dictionary in the same or different XML document.

The following examples shows two instances of dictionaries:

```

<gml:Dictionary gml:id="rockTypes">
  <gml:description>A simple dictionary of rock types using components from gmlBase</gml:description>
  <gml:name>Example dictionary of rock types</gml:name>
  <gml:dictionaryEntry>
    <gml:Definition gml:id="granite">
      <gml:description>A igneous rock normally composed of quartz, two feldspars and optional mica</gml:description>
      <gml:name>Granite</gml:name>
    </gml:Definition>
  </gml:dictionaryEntry>
  <gml:dictionaryEntry>
    <gml:Definition gml:id="sst">
      <gml:description>A detrital sedimentary rock normally composed of siliceous grains</gml:description>
      <gml:name>Sandstone</gml:name>
    </gml:Definition>
  </gml:dictionaryEntry>
  <gml:indirectEntry>
    <gml:DefinitionProxy gml:id="lst">
      <gml:definitionRef xlink:href="http://my.big.org/definitions/geology/limestone"/>
    </gml:DefinitionProxy>
  </gml:indirectEntry>
</gml:Dictionary>

<gml:Dictionary gml:id="AbridgedGMLdictionary">
  <gml:description>Abridged GML dictionary. See section 4 Terms and definitions for the rest.</gml:description>
  <gml:name>GML dictionary</gml:name>
  <gml:dictionaryEntry>
    <gml:Definition gml:id="association">
      <gml:description>A structural relationship that describes a set of links, in which a link is a connection among objects; the semantic relationship between two or more classifiers that involves the connections among their instances (Booch, 1999).</gml:description>
      <gml:name>association</gml:name>
    </gml:Definition>

```

```

</gml:dictionaryEntry>
<gml:dictionaryEntry>
  <gml:DefinitionCollection gml:id="attribute">
    <gml:description>named property</gml:description>
    <gml:name>attribute</gml:name>
    <gml:definitionMember>
      <gml:Definition gml:id="attribute_in_UML">
        <gml:description>Named property of a class that describes the range of values that instances of the property may
hold. (Booch, 1999)</gml:description>
        <gml:name codeSpace="UML">attribute</gml:name>
        </gml:Definition>
      </gml:definitionMember>
      <gml:definitionMember>
        <gml:Definition gml:id="attribute_in_XML">
          <gml:description>An information item in the XML Information Set [Infoset] </gml:description>
          <gml:name codeSpace="XML">attribute</gml:name>
          </gml:Definition>
        </gml:definitionMember>
      </gml:DefinitionCollection>
    </gml:dictionaryEntry>
  </gml:dictionaryEntry>
  <gml:DefinitionCollection gml:id="property">
    <gml:description>A characteristic of an object</gml:description>
    <gml:name>property</gml:name>
    <gml:definitionMember>
      <gml:Definition gml:id="property_in_GML">
        <gml:description>A characteristic of a GML object.</gml:description>
        <gml:name codeSpace="GML">property</gml:name>
        </gml:Definition>
      </gml:definitionMember>
      <gml:definitionMember>
        <gml:DefinitionCollection gml:id="property_in_UML">
          <gml:description>A characteristic of a UML object.</gml:description>
          <gml:name codeSpace="UML">property</gml:name>
          <gml:dictionaryEntry xlink:href="#association"/>
          <gml:dictionaryEntry xlink:href="#attribute_in_UML"/>
          </gml:DefinitionCollection>
        </gml:definitionMember>
      </gml:DefinitionCollection>
    </gml:dictionaryEntry>
  <gml:indirectEntry>
    <gml:DefinitionProxy gml:id="property_proxy">
      <gml:name>property</gml:name>
      <gml:definitionRef xlink:href="#property"/>
    </gml:DefinitionProxy>
  </gml:indirectEntry>
</gml:Dictionary>

```

### 15.2.5 Using Definitions and Dictionaries

Dictionaries and Definitions are GML Objects, so may be found in independent GML data instance documents.

In application schemas it might be useful to attach a Dictionary or Definition Collection, or Definitions to a feature collection in order to record definitions used in properties of members of the collection.

## 16 GML schemas – units, measures and values

### 16.1 Introduction

Several GML schemas introduce components that concern or require quantitative values which use a reference scale or units of measure. In Clause 7.2, basicTypes.xsd provides MeasureType, MeasureListType

and MeasureOrNullListType definitions to enable GML properties and objects to carry units of measure, according to the following pattern:

```
abc:length uom = "#m">100</abc:length>
```

The attribute “uom” means “unit of measure” and holds a URI which refers to a resource that defines the units. The following schema documents describe components concerning this topic:

- units.xsd declares a set of components for defining units of measure
- measures.xsd declares a set of typed measures;
- valueObjects.xsd describes structures for aggregates and lists of measures.

The schema documents units.xsd, measures.xsd, and valueObjects.xsd define components for the description of measurement scales, typed measures, and generic (possibly complex) values, respectively.

## 16.2 Units schema

Several GML schemas define components that concern or require a reference scale or units of measure. Units are required for quantities that may occur as values of properties of feature types, as the results of observations, in the range parameters of a coverage, and for measures used in Coordinate Reference System definitions. The schema document units.xsd defines components to support the definition of units of measure. The units schema is listed in Annex C; it is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:units:v3.0
```

The basic unit definition is an extension of the general gml:Definition element defined in clause 15.2. Three specialized elements for unit definition are further derived from this.

This model is based on the SI system of units [ISO 1000], which distinguishes between Base Units and Derived Units.

- **Base Units** are the preferred units for a set of orthogonal fundamental quantities which define the particular system of units, which may not be derived by combination of other base units.
- **Derived Units** are the preferred units for other quantities in the system, which may be defined by algebraic combination of the base units.

In some application areas **Conventional units** are used, which may be converted to the preferred units using a scaling factor or a formula which defines a re-scaling and offset. The set of preferred units for all quantity types in a particular system of units is composed of the union of its base units and derived units.

### 16.2.1 Using Unit Definitions

Unit definitions are substitutable for the gml:Definition element declared as part of the dictionary model. A dictionary that contains only unit definitions and references to unit definitions is a units dictionary.

### 16.2.2 gml:unitOfMeasure, gml:UnitOfMeasureType

The element gml:unitOfMeasure is a property element to refer to a unit of measure. It is declared in the schema as follows:

```
<element name="unitOfMeasure" type="gml:UnitOfMeasureType"/>
<complexType name="UnitOfMeasureType">
  <sequence/>
  <attribute name="uom" type="anyURI" use="required"/>
```

```
</complexType>
```

This is an empty element which carries a reference to a unit of measure definition. This element may appear in a data instance as follows:

```
<unitOfMeasure uom="#m"/>
<unitOfMeasure uom="http://my.standards.org/units/length/metre"/>
```

If the unit of measure definition is within the same XML document, the URI may be a barename Xpointer, in which the "#" symbol is prepended to the value of the attribute of XML type ID carried by the definition (e.g. gml:id). For convenience, the ID may be a mnemonic abbreviation of the unit name. Thus, in the first case the reference is to an element in the same document which carries gml:id="m". In the second example the reference is to a definition provided by an external service.

### 16.2.3 gml:UnitDefinition, gml:UnitDefinitionType

A UnitDefinition is a general definition of a unit of measure. This generic element is used only for units for which no relationship with other units or units systems is known. It is declared in the schema as follows:

```
<element name="UnitDefinition" type="gml:UnitDefinitionType" substitutionGroup="gml:Definition"/>
<complexType name="UnitDefinitionType">
  <complexContent>
    <extension base="gml:DefinitionType">
      <sequence>
        <element ref="gml:quantityType"/>
        <element ref="gml:catalogSymbol" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The content model of gml:UnitDefinition adds two additional properties to gml:Definition (described in clause 15.2.1), gml:quantityType and gml:catalogSymbol. gml:quantityType.

### 16.2.4 gml: quantityType

The gml:quantityType property indicates the phenomenon to which the units apply. It is declared as follows:

```
<element name="quantityType" type="gml:StringOrRefType"/>
```

This element contains an informal description of the phenomenon or type of quantity that is measured or observed. For example, "length", "angle", "time", "pressure", or "temperature". When the quantity is the result of an observation or measurement, this term is known as Observable Type or Measurand.

### 16.2.5 gml:catalogSymbol

The catalogSymbol is the preferred lexical symbol used for this unit of measure. It is declared as follows:

```
<element name="catalogSymbol" type="gml:CodeType"/>
```

The "codeSpace" attribute in "CodeType" identifies a namespace for the catalog symbol value, and might reference the external catalog. The "string" value in "CodeType" contains the value of a symbol that should be unique within this catalog namespace. This symbol often appears explicitly in the catalog, but it could be a combination of symbols using a specified algebra of units. For example, the symbol "cm" might indicate that it is the "m" symbol combined with the "c" prefix.

### 16.2.6 gml:BaseUnit, gml:BaseUnitType, gml:unitsSystem

A base unit is a unit of measure that cannot be derived by combination of other base units within a particular system of units. For example, in the SI system of units, the base units are metre, kilogram, second, Ampere, Kelvin, mole, and candela, for the quantity types length, mass, time interval, electric current, thermodynamic temperature, amount of substance and luminous intensity, respectively.

This is supported using the gml:BaseUnit element which is declared as follows:

```
<element name="BaseUnit" type="gml:BaseUnitType" substitutionGroup="gml:UnitDefinition"/>

<complexType name="BaseUnitType">
  <complexContent>
    <extension base="gml:UnitDefinitionType">
      <sequence>
        <element name="unitsSystem" type="gml:ReferenceType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

gml:BaseUnit extends generic gml:UnitDefinition with the property gml:unitsSystem, which carries a reference to the units system to which this base unit is asserted to belong.

### 16.2.7 gml:DerivedUnit, gml:DerivedUnitType

Derived units are defined by combination of other units. Derived units are used for quantities other than those corresponding to the base units, such as hertz (s<sup>-1</sup>) for frequency, Newton (kg.m/s<sup>2</sup>) for force. Derived units based directly on base units are usually preferred for quantities other than the fundamental quantities within a system. If a derived unit is not the preferred unit, the ConventionalUnit element should be used instead. The gml:DerivedUnit element is declared as follows:

```
<element name="DerivedUnit" type="gml:DerivedUnitType" substitutionGroup="gml:UnitDefinition"/>

<complexType name="DerivedUnitType">
  <complexContent>
    <extension base="gml:UnitDefinitionType">
      <sequence>
        <element ref="gml:derivationUnitTerm" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The gml:DerivedUnit extends gml:UnitDefinition with the property gml:derivationUnitTerms.

### 16.2.8 gml:derivationUnitTerms, gml:DerivationUnitTermType

A set of gml:derivationUnitTerm elements describes a derived unit of measure. Each element carries an integer exponent. The terms are combined by raising each referenced unit to the power of their exponent and forming the product. The element gml:derivationUnitTerm is declared as follows:

```
<element name="derivationUnitTerm" type="gml:DerivationUnitTermType"/>

<complexType name="DerivationUnitTermType">
  <complexContent>
    <extension base="gml:UnitOfMeasureType">
      <attribute name="exponent" type="integer"/>
    </extension>
  </complexContent>
</complexType>
```

```
</complexType>
```

This unit term references another unit of measure (uom) and provides an integer exponent applied to that unit in defining the compound unit. The exponent can be positive or negative, but not zero.

### 16.2.9 gml:ConventionalUnit, gml:ConventionalUnitType

Conventional units that are neither base units nor defined by direct combination of base units are used in many application domains. For example electronVolt for energy, feet and nautical miles for length. In most cases there is a known, usually linear, conversion to a preferred unit which is either a base unit or derived by direct combination of base units. The gml:ConventionalUnit element is declared as follows:

```
<element name="ConventionalUnit" type="gml:ConventionalUnitType" substitutionGroup="gml:UnitDefinition"/>
<complexType name="ConventionalUnitType">
  <complexContent>
    <extension base="gml:UnitDefinitionType">
      <sequence>
        <choice>
          <element ref="gml:conversionToPreferredUnit"/>
          <element ref="gml:roughConversionToPreferredUnit"/>
        </choice>
        <element ref="gml:DerivationUnitTerm" minOccurs="0" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The gml:ConventionalUnit extends gml:UnitDefinition with a property that describes a conversion to a preferred unit for this quantity. When the conversion is exact, the element gml:conversionToPreferredUnit should be used, or when the conversion is not exact the element gml:roughConversionToPreferredUnit is available. Both of these elements have the same content model. The gml:derivationUnitTerm property defined above is included to allow a user to optionally record how this unit may be derived from other ("more primitive") units.

### 16.2.10 gml:conversionToPreferredUnit, gml:roughConversionToPreferredUnit, gml:ConversionToPreferredUnitType, gml:FormulaType

The elements gml:conversionToPreferredUnit and gml:roughConversionToPreferredUnit represent parameters used to convert conventional units to preferred units for this quantity type. A preferred unit is either a Base Unit or a Derived Unit that is selected for all values of one quantity type. These conversions are declared in the schema as follows:

```
<element name="conversionToPreferredUnit" type="gml:ConversionToPreferredUnitType"/>
<element name="roughConversionToPreferredUnit" type="gml:ConversionToPreferredUnitType"/>
<complexType name="ConversionToPreferredUnitType">
  <complexContent>
    <extension base="gml:UnitOfMeasureType">
      <choice>
        <element name="factor" type="double"/>
        <element name="formula" type="gml:FormulaType"/>
      </choice>
    </extension>
  </complexContent>
</complexType>
```

The inherited attribute "uom" references the preferred unit that this conversion applies to. The conversion of a unit to the preferred unit for this quantity type is specified by an arithmetic conversion (scaling and/or offset). The content model extends gml:UnitOfMeasureType, which has a mandatory attribute uom which identifies

the preferred unit for the quantity type that this conversion applies to. The conversion is specified by a choice of

`gml:factor`, which defines the scale factor

`gml:formula`, which defines a formula

by which a value using the conventional unit of measure can be converted to obtain the corresponding value using the preferred unit of measure. The model for the formula is given as follows:

```
<complexType name="FormulaType">
  <sequence>
    <element name="a" type="double" minOccurs="0"/>
    <element name="b" type="double"/>
    <element name="c" type="double"/>
    <element name="d" type="double" minOccurs="0"/>
  </sequence>
</complexType>
```

This formula defines the parameters of a simple formula by which a value using the conventional unit of measure can be converted to the corresponding value using the preferred unit of measure. The formula element contains elements `a`, `b`, `c` and `d`, whose values use the XML Schema type "double". These values are used in the formula  $y = (a + bx) / (c + dx)$ , where  $x$  is a value using this unit, and  $y$  is the corresponding value using the base unit. The elements `a` and `d` are optional, and if values are not provided, those parameters are considered to be zero. If values are not provided for both `a` and `d`, the formula is equivalent to a fraction with numerator and denominator parameters.

### 16.2.11 Example of units dictionary

This dictionary contains definitions corresponding to all the base and derived units defined by in the SI system [SI], plus a selection of conventional units to illustrate the usage of these components.

```
<gml:Dictionary gml:id="unitsDictionary">

## 16.3 Measures schema

A schema for specific measure types is listed in Annex C; it is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:measures:v3.0
```

`gml:MeasureType` is defined in `basicTypes.xsd`. The measure types defined here correspond with a set of convenience measure types described in ISO 19103. The XML implementation is based on the XML Schema simpleType "double" which supports both decimal and scientific notation, and includes an XML attribute "uom" which refers to the units of measure for the value. Note that, there is no requirement to *store* values using any particular format, and applications receiving elements of this type may choose to coerce the data to any other type as convenient.

### 16.3.1 gml:measure

This is the value of a quantity, together with its units. It is declared as follows:

```
<element name="measure" type="gml:MeasureType"/>
```

In an instance document the element might appear:

```
<gml:measure uom="#m">1.76</gml:measure>
```

The XML attribute `uom` is used to hold a reference to the scale or units by which the amount should be multiplied.

The "uom" attribute uses a URI to refer to a unit of measure definition. The definition may be within the same XML document or external. A definition within the same document would normally use the `UnitDefinition` element described above, which carries an ID handle as the value of its `gml:id` attribute. A measure element referring to this definition would normally use the abbreviated Xpointer form of URI.

For convenience the handle on the definition (the value of the `gml:id` attribute) will normally be mnemonic based on the unit name, such as "m" for metre. So if the definition is in the same document as the reference, the URI may be an abbreviated Xpointer reference [URI] which is presented with the "#" symbol prepended to the handle, i.e. "#m" as in this example.

### 16.3.2 Scalar measure types

A set of specific measure types are defined as vacuous extensions (i.e. aliases) of `gml:MeasureType`. A prototypical definition is as follows:

```
<complexType name="LengthType">
  <simpleContent>
    <extension base="gml:MeasureType"/>
  </simpleContent>
</complexType>
```

This content model supports the description of a length (or distance) quantity, with its units. The unit of measure referenced by `uom` shall be suitable for a length, such as metres or feet.

The other measure types that are defined following this pattern are: `ScaleType`, `GridLengthType`, `AreaType`, `VolumeType`, `SpeedType`, `TimeType`.

Elements using these content models might appear in a data instance as follows:

```
<my:length uom="#m">1.76</my:length>
<my:scale uom="#percent">20.</my:scale>
<my:gridLength uom="#pixelSpacing">480</my:gridLength>
<my:gridLength uom="#imageHeight">0.002083333333333</my:gridLength>
<my:area uom="#Ha">1.76</my:area>
```

```

<my:volume uom="#l">0.45</my:volume>
<my:speed uom="#kmph">73.0</my:speed>
<my:time uom="#minutes">30.</my:time>

```

Note that the last element addresses the same functional requirements as the elements in the **gml:\_timeLength** substitution group, defined in clause 14.

### 16.3.3 gml:angle

The gml:angle element is used to record the value of an angle quantity as a single number, with its units. gml:AngleType is derived trivially from gml:MeasureType using the method described above, with the restriction that the unit of measure referenced by **uom** shall be suitable for an angle, such as degrees or radians. It is declared in the schema as follows:

```

<element name="angle" type="gml:AngleType"/>

<complexType name="AngleType">
  <simpleContent>
    <extension base="gml:MeasureType"/>
  </simpleContent>
</complexType>

```

In an instance document the element might appear:

```

<gml:angle uom="#gradians">95.</gml:angle>

```

### 16.3.4 gml:dmsAngle

The gml:dmsAngle element is used to record the value of an angle in degree-minute-second or degree-minute format. It uses the following schema declarations:

```

<element name="dmsAngle" type="gml:DMSAngleType"/>

<complexType name="DMSAngleType">
  <sequence>
    <element ref="gml:degrees"/>
    <choice minOccurs="0">
      <element ref="gml:decimalMinutes"/>
      <sequence>
        <element ref="gml:minutes"/>
        <element ref="gml:seconds" minOccurs="0"/>
      </sequence>
    </choice>
  </sequence>
</complexType>

<element name="degrees" type="gml:DegreesType"/>

<complexType name="DegreesType">
  <simpleContent>
    <extension base="gml:DegreeValueType">
      <attribute name="direction">
        <simpleType>
          <restriction base="string">
            <enumeration value="N"/>
            <enumeration value="E"/>
            <enumeration value="S"/>
            <enumeration value="W"/>
            <enumeration value="+"/>
          </restriction>
        </simpleType>
      </attribute>
    </extension>
  </simpleContent>
</complexType>

```

```

    <enumeration value="-"/>
  </restriction>
</simpleType>
</attribute>
</extension>
</simpleContent>
</complexType>

<simpleType name="DegreeValueType">
  <restriction base="nonNegativeInteger">
    <maxInclusive value="359"/>
  </restriction>
</simpleType>

<element name="decimalMinutes" type="gml:DecimalMinutesType"/>

<simpleType name="DecimalMinutesType">
  <restriction base="decimal">
    <minInclusive value="0.00"/>
    <maxExclusive value="60.00"/>
  </restriction>
</simpleType>

<element name="minutes" type="gml:ArcMinutesType"/>

<simpleType name="ArcMinutesType">
  <restriction base="nonNegativeInteger">
    <maxInclusive value="59"/>
  </restriction>
</simpleType>

<element name="seconds" type="gml:ArcSecondsType"/>

<simpleType name="ArcSecondsType">
  <restriction base="decimal">
    <minInclusive value="0.00"/>
    <maxExclusive value="60.00"/>
  </restriction>
</simpleType>

```

In an instance document the element might appear in one of the following forms:

```

<gml:dmsAngle>
  <gml:degrees direction="S">35</gml:degrees>
  <gml:minutes>45</gml:minutes>
  <gml:seconds>21.98</gml:seconds>
</gml:dmsAngle>

<gml:dmsAngle>
  <gml:degrees direction="S">35</gml:degrees>
  <gml:decimalMinutes>45.43</gml:decimalMinutes>
</gml:dmsAngle>

```

### 16.3.5 gml:degrees

The **degrees** element allows an integer number of degrees with identification of the angle direction. This element is intended to be used within geographic positions, and has an XML attribute **direction** that can take values

"N" or "S" for Latitude, meaning North or South of the equator;

"E" or "W" for Longitude, meaning East or West of the prime meridian;

"+" or "-" for other angles, in the specified rotational direction from a specified reference direction.

### 16.3.6 gml:decimalMinutes

Decimal number of arc-minutes for use within a degree-minute angular value.

### 16.3.7 gml:minutes

Integer number of arc-minutes for use within a degree-minute-second angular value.

### 16.3.8 gml:seconds

Number of arc-seconds for use within a degree-minute-second angular value.

### 16.3.9 gml:AngleChoiceType

To support the choice of either encoding for angles in a content model, a convenience type **gml:AngleChoiceType** is provided. This element contains another element, either a angle or a dmsAngle. It is declared in the schema as follows:

```
<complexType name="AngleChoiceType">
  <choice>
    <element ref="gml:angle"/>
    <element ref="gml:dmsAngle"/>
  </choice>
</complexType>
```

In an instance document an element of this type might appear:

```
<my:angle>
  <gml:angle uom="#gradians">95.</gml:simpleAngle>
</my:angle>

<my:angle>
  <gml:dmsAngle>
    <gml:degrees direction="S">35</gml:degrees>
    <gml:decimalMinutes>45.43</gml:decimalMinutes>
  </gml:dmsAngle>
</my:angle>
```

## 16.4 Value Objects schema

### 16.4.1 Introduction

The schema document valueObjects.xsd describing components for generic Values is listed in Annex C. It is identified by the following location-independent name (using URN syntax):

urn:opengis:specification:gml:schema-xsd:valueObjects:v3.0

The elements declared in valueObjects.xsd build on elements and types from other GML schemas, in particular `_TimeObject` from temporal.xsd, `_Geometry` from geometryBasic0d1d.xsd, and the following types from basicTypes.xsd: `MeasureType`, `MeasureListType`, `CodeType`, `CodeOrNullListType`, `BooleanOrNullListType`, `IntegerOrNullList`.

Of particular interest are elements declared in valueObjects.xsd that are the heads of substitution groups, and one named choice group. These are the primary reason for the value objects schema, since they can act as variables in the definition of content models, such as Observations, when it is desired to permit alternative value types to occur some of which may have complex content such as arrays, geometry and time objects, and where it is useful not to prescribe the actual value type in advance. The members of the groups include quantities, category classifications, Boolean, count, temporal and spatial values, and aggregates of these.

NOTE The elements declared in this schema are used for **direct representation** of values. Their content models are in general not derived from gml:AbstractGMLType and they do not carry an identifier.

### 16.4.2 Value element hierarchy

The component hierarchy is illustrated in the following UML class diagram. UML generalization relationships are used to indicate XML Schema substitution group and choice group membership. UML composition relationships are used to indicate membership in an XML Schema type content model.

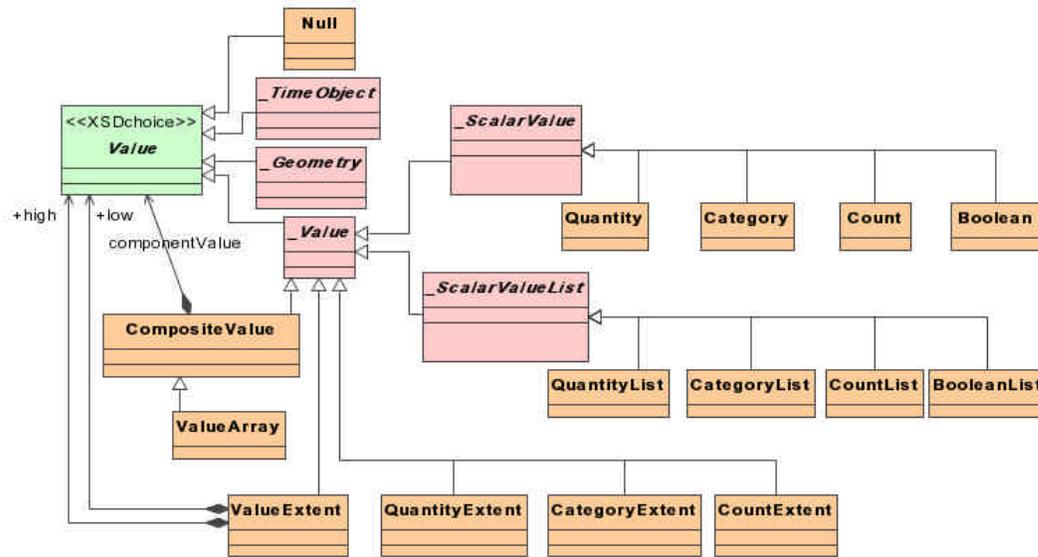

Figure 16.4.1 Substitution groups and composition relationships in the value schema

The following relationships are defined in the valueObjects.xsd schema:

- Concrete elements Quantity, Category, Count and Boolean are substitutable for the abstract element `_ScalarValue`.
- Concrete elements QuantityList, CategoryList, CountList and BooleanList are substitutable for the abstract element `_ScalarValueList`.
- Concrete element ValueArray is substitutable for the concrete element CompositeValue.
- Abstract elements `_ScalarValue` and `_ScalarValueList`, and concrete elements CompositeValue, ValueExtent, CategoryExtent, CountExtent and QuantityExtent are substitutable for abstract element `_Value`.
- Abstract elements `_Value`, `_TimeObject` (from temporal.xsd) and `_Geometry` (from geometryBasic0d1d.xsd), and concrete element Null (from gmlBase.xsd) are all in a choice group named Value, which is used for compositing in CompositeValue and ValueExtent.
- Schemas which need values may use the abstract element `_Value` in a content model in order to permit any of the `_ScalarValue`'s, `_ScalarValueList`'s, CompositeValue or ValueExtent to occur in an instance, or the named group Value to also permit TimeObject's, Geometry's, and Null's.

### 16.4.3 gml:Boolean, gml:BooleanList

For recording a value or list of values from two-valued logic, using the XML Schema boolean type. These elements use the following schema declarations:

```
<element name="Boolean" type="boolean" substitutionGroup="gml:_ScalarValue"/>
```

```
<element name="BooleanList" type="gml:booleanOrNullList" substitutionGroup="gml:_ScalarValueList"/>
```

These elements are described in clause 7.3.4.1.

In an instance the following examples may be found:

```
<gml:Boolean>1</gml:Boolean>
```

```
<gml:Boolean>>false</gml:Boolean>
```

```
<gml:BooleanList>1 missing 0 1 1 http://my.big.org/explanations/theDogAtelt 0 1</gml:BooleanList>
```

These examples illustrate the use of the various Boolean values {1, 0, true, false} and also the fact that null values such as “missing” or a URI can be embedded within a list.

#### 16.4.4 gml:Category, gml:CategoryList

For recording terms representing a classification. These elements use the following schema declarations:

```
<element name="Category" type="gml:CodeType" substitutionGroup="gml:_ScalarValue"/>
```

```
<element name="CategoryList" type="gml:CodeOrNullListType" substitutionGroup="gml:_ScalarValueList"/>
```

A Category has an optional XML attribute **codeSpace**, whose value is a URI which identifies a dictionary, codelist or authority for the term. In an instance the following examples may be found:

```
<gml:Category>good</gml:Category>
```

```
<gml:Category codeSpace="http://my.big.org/dictionaries/rocktypes">Syenite</gml:Category>
```

```
<gml:CategoryList codeSpace="http://my.big.org/dictionaries/rocktypes">Syenite Granite missing Tuff</gml:CategoryList>
```

```
<gml:CategoryList codeSpace="http://my.big.org/species">bettong numbat phasogale wallaby possum</gml:CategoryList>
```

#### 16.4.5 gml:Count, gml:CountList

For recording integers representing a rate of occurrence. These elements use the following schema declarations:

```
<element name="Count" type="integer" substitutionGroup="gml:_ScalarValue"/>
```

```
<element name="CountList" type="gml:integerOrNullList" substitutionGroup="gml:_ScalarValueList"/>
```

In an instance the following examples may be found:

```
<gml:Count>513</gml:Count>
```

```
<gml:CountList>34 56 2 inapplicable 153</gml:CountList>
```

#### 16.4.6 gml:Quantity, gml:QuantityList

For recording numeric values with a scale. The content of the element is an amount using the XML Schema type double which permits decimal or scientific notation. These elements use the following schema declarations:

```
<element name="Quantity" type="gml:MeasureType" substitutionGroup="gml:_ScalarValue"/>
```

```
<element name="QuantityList" type="gml:MeasureOrNullListType" substitutionGroup="gml:_ScalarValueList"/>
```

An XML attribute **uom** (“unit of measure”) is required, whose value is a URI which identifies the definition of a ratio scale or units by which the numeric value shall be multiplied, or an interval or position scale on which the value occurs. In an instance the following examples may be found:

```
<gml:Quantity uom="#m">4.32e-4</gml:Quantity>
<gml:QuantityList uom="#C">21. 37. withheld 25.</gml:QuantityList>
```

#### 16.4.7 gml:\_Value, gml:\_ScalarValue, gml:\_ScalarValueList

Value is an abstract element which acts as the head of a substitution group which contains \_ScalarValue, \_ScalarValueList, CompositeValue and ValueExtent, and (transitively) the elements in their substitution groups.

ScalarValue is an abstract element which acts as the head of a substitution group which contains Boolean, Category, Count and Quantity, and (transitively) the elements in their substitution groups.

ScalarValueList is an abstract element which acts as the head of a substitution group which contains BooleanList, CategoryList, CountList and QuantityList, and (transitively) the elements in their substitution groups.

These elements use the following schema declarations:

```
<element name="_Value" abstract="true" substitutionGroup="gml:_Object">
<element name="_ScalarValue" abstract="true" substitutionGroup="gml:_Value"/>
<element name="_ScalarValueList" abstract="true" substitutionGroup="gml:_Value"/>
```

These elements may be used in an application schema as variables, so that in an XML instance document any member of its substitution group may occur.

#### 16.4.8 gml:Value

This is a convenience choice group which unifies generic Values defined in this schema document with Geometry and Temporal objects and the Measures described above, so that any of these may be used within aggregate Values. This element uses the following schema declaration:

```
<group name="Value">
  <choice>
    <element ref="gml:_Value"/>
    <element ref="gml:_Geometry"/>
    <element ref="gml:_TimeObject"/>
    <element ref="gml:Null"/>
    <element ref="gml:measure"/>
  </choice>
</group>
```

#### 16.4.9 gml:valueProperty, gml:valueComponent, gml:valueComponents

Elements that instantiates a GML property which refers to, or contains, a Value or Values. These elements use the following schema declarations:

```
<element name="valueProperty" type="gml:ValuePropertyType"/>
<element name="valueComponent" type="gml:ValuePropertyType"/>

<complexType name="ValuePropertyType">
  <sequence minOccurs="0">
    <group ref="gml:Value"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

```
<element name="valueComponents" type="gml:ValueArrayPropertyType"/>
```

```
<complexType name="ValueArrayPropertyType">  
  <sequence>  
    <group ref="gml:Value" maxOccurs="unbounded"/>  
  </sequence>  
</complexType>
```

Note that both ValuePropertyType and ValueArrayPropertyType have the group named “Value” as their content. This means that any of the elements in the Value choice group, or in the substitution groups of the members of the choice group can occur as the content of a valueProperty.

The valueProperty element is a convenience element for general use. The valueComponent and valueComponents elements are specifically used in compositing.

#### 16.4.10 gml:CompositeValue

CompositeValue is an aggregate value built from other Values using the Composite pattern. It contains zero or an arbitrary number of valueComponent elements, and zero or one valueComponents elements. It may be used for strongly coupled aggregates (vectors, tensors) or for arbitrary collections of values. This element uses the following schema declarations:

```
<element name="CompositeValue" type="gml:CompositeValueType" substitutionGroup="gml:_Value"/>
```

```
<complexType name="CompositeValueType">  
  <complexContent>  
    <extension base="gml:AbstractGMLType">  
      <sequence>  
        <element ref="gml:valueComponent" minOccurs="0" maxOccurs="unbounded"/>  
        <element ref="gml:valueComponents" minOccurs="0"/>  
      </sequence>  
    </extension>  
  </complexContent>  
</complexType>
```

In an instance a CompositeValue may appear as in the following examples:

```
<gml:CompositeValue>  
  <gml:valueComponent>  
    <gml:QuantityList uom="#C">21. 37. withheld 25.</gml:QuantityList>  
  </gml:valueComponent>  
  <gml:valueComponent>  
    <gml:Category>good</gml:Category>  
  </gml:valueComponent>  
  <gml:valueComponent>  
    <gml:Null>template</gml:Null>  
  </gml:valueComponent>  
  <gml:valueComponents>  
    <gml:Point srsName="urn:EPSG:geographicCRS:4326"><gml:pos>171. -32.</gml:pos></gml:Point>  
    <gml:Point srsName="urn:EPSG:geographicCRS:4326"><gml:pos>170. -35.</gml:pos></gml:Point>  
    <gml:Point srsName="urn:EPSG:geographicCRS:4326"><gml:pos>174. -37.</gml:pos></gml:Point>  
  </gml:valueComponents>  
</gml:CompositeValue>
```

```
<gml:CompositeValue>  
  <gml:valueComponents>  
    <gml:Point srsName="urn:EPSG:geographicCRS:4326"><gml:pos>-67.563 -13.834</gml:pos></gml:Point>  
    <gml:Quantity uom="#km">632.</gml:Quantity>  
    <gml:TimeInstant><gml:timePosition>1994-06-09T00:33:16.4</gml:timePosition></gml:TimeInstant>  
    <gml:Quantity uom="#mom">-1.00</gml:Quantity>  
    <gml:Quantity uom="#mom">0.92</gml:Quantity>  
    <gml:Quantity uom="#mom">0.09</gml:Quantity>  
  </gml:valueComponents>  
</gml:CompositeValue>
```

```

<gml:Quantity uom="#mom">-1.69</gml:Quantity>
<gml:Quantity uom="#mom">-0.09</gml:Quantity>
<gml:Quantity uom="#mom">-0.37</gml:Quantity>
</gml:valueComponents>
</gml:CompositeValue>

```

#### 16.4.11 gml:ValueArray

A Value Array is used for homogeneous arrays of primitive and aggregate values.

The member values may be scalars, composites, arrays or lists. This element uses the following schema declarations:

```

<element name="ValueArray" type="gml:ValueArrayType" substitutionGroup="gml:CompositeValue">
  <annotation>
    <appinfo>
      <sch:pattern name="Check either codeSpace or uom not both">
        <sch:rule context="gml:ValueArray">
          <sch:report test="@codeSpace and @uom">ValueArray may not carry both a reference to a codeSpace and a
uom</sch:report>
        </sch:rule>
      </sch:pattern>
      <sch:pattern name="Check components are homogeneous">
        <sch:rule context="gml:ValueArray">
          <sch:assert test="count(gml:valueComponent/*) = count(gml:valueComponent/*[name() =
name(..../gml:valueComponent[1]/*[1])])">All components of <sch:name/> shall be of the same type</sch:assert>
          <sch:assert test="count(gml:valueComponents/*) = count(gml:valueComponents/*[name() = name(..*[1])])">All
components of <sch:name/> shall be of the same type</sch:assert>
        </sch:rule>
      </sch:pattern>
    </appinfo>
  </annotation>
</element>

<complexType name="ValueArrayType">
  <complexContent>
    <extension base="gml:CompositeValueType">
      <attributeGroup ref="gml:referenceSystem"/>
    </extension>
  </complexContent>
</complexType>

<attributeGroup name="referenceSystem">
  <attribute name="codeSpace" type="anyURI" use="optional"/>
  <attribute name="uom" type="anyURI" use="optional"/>
</attributeGroup>

```

ValueArray has the same content model as CompositeValue, but the member values shall be homogeneous. The element declaration contains a Schematron constraint which expresses this restriction precisely. Since the members are homogeneous, the referenceSystem (**uom**, **codeSpace**) may be specified on the ValueArray itself and inherited by all the members if desired.

The ValueArray element may appear in instances as follows.

In the first example a set of Points are each the value of a valueComponent property. One of the values is provided by-reference, using the standard xlink:href syntax:

```

<gml:ValueArray>
  <gml:valueComponent>
    <gml:Point srsName="urn:EPSG:geographicCRS:63266405">
      <gml:pos>-32. 171.</gml:pos>
    </gml:Point>
  </gml:valueComponent>
  <gml:valueComponent>

```

```

<gml:Point srsName="urn:EPSG:geographicCRS: 63266405">
  <gml:pos>-35. 170.</gml:pos>
</gml:Point>
</gml:valueComponent>
<gml:valueComponent xlink:href="http://my.big.org/locations/points/point456"/>
</gml:ValueArray>

```

In the second example a set of Quantities are contained within a valueComponents property. One of the values is not available, indicated by a Null:

```

<gml:ValueArray>
  <gml:valueComponents>
    <gml:Quantity uom="#C">21.</gml:Quantity>
    <gml:Quantity uom="#C">37.</gml:Quantity>
    <gml:Null>missing</gml:Null>
  </gml:valueComponents>
</gml:ValueArray>

```

Note that a\_ScalarValueList is usually preferred for arrays of Scalar Values since this is a more efficient encoding. The information in the previous example can be expressed:

```

<gml:QuantityList uom="#C">21. 37. missing</gml:QuantityList>

```

However, if the values of the components are not scalars, then the explicit form is required.

#### 16.4.12 Typed ValueExtents: gml:CategoryExtent, gml:CountExtent, gml:QuantityExtent

Three elements are provided for typed value extents, for categories, counts and quantities. Their content models are defined by restricting the relevant scalar list types to contain exactly two items as follows:

```

<element name="CategoryExtent" type="gml:CategoryExtentType" substitutionGroup="gml:_Value"/>
  <complexType name="CategoryExtentType">
    <simpleContent>
      <restriction base="gml:CodeOrNullListType">
        <length value="2"/>
      </restriction>
    </simpleContent>
  </complexType>

<element name="CountExtent" type="gml:CountExtentType" substitutionGroup="gml:_Value"/>
  <simpleType name="CountExtentType">
    <restriction base="gml:integerOrNullList">
      <length value="2"/>
    </restriction>
  </simpleType>

<element name="QuantityExtent" type="gml:QuantityExtentType" substitutionGroup="gml:_Value"/>
  <complexType name="QuantityExtentType">
    <simpleContent>
      <restriction base="gml:MeasureOrNullListType">
        <length value="2"/>
      </restriction>
    </simpleContent>
  </complexType>

```

A gml:QuantityExtent element or another element using this type will contain two values and a scale as follows:

```

<gml:QuantityExtent uom="#mm">0. 9.5</gml:QuantityExtent>

```

An element of `gml:CategoryExtentType` is useful if the `codeSpace` defines a set of ordered terms, for example:

```
<my:AgeRange codeSpace="http://iugg.org/geologicalTimePeriods">Cambrian Devonian</my:AgeRange>
```

Any value extent may describe a single-ended interval by using a Null value for one of the limits, for example:

```
<gml:CountExtent>53 inapplicable</gml:CountExtent>
```

describes the integers starting with 53.

#### 16.4.13 `gml:BooleanPropertyType`, `gml:CategoryPropertyType`, `gml:CountPropertyType`, `gml:QuantityPropertyType`

A set of convenience types are provided for properties whose content is a specific member of the `gml:_ScalarValue` substitution group. Their definitions follow the same pattern, as exemplified by the definition of `gml:BooleanPropertyType`:

```
<complexType name="BooleanPropertyType">
  <complexContent>
    <restriction base="gml:ValuePropertyType">
      <sequence >
        <element ref="gml:Boolean" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

## 17 GML schemas – directions

### 17.1 Direction schema

The direction schema, `direction.xsd` provides the GML Application Schema developer with a standard property element to describe direction, and associated objects that can be used to express orientation, direction, heading, bearing or other directional aspects of geographic features. The schema is listed in Annex C. It is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:direction:v3.1.0
```

#### 17.1.1 `gml:direction`, `gml:DirectionPropertyType`

The property `gml:direction` is intended as a property to be assigned to features defined in a GML application schema. It is declared in the schema as follows:

```
<element name="direction" type="gml:DirectionPropertyType"/>
<complexType name="DirectionPropertyType">
  <annotation>
    <documentation/>
  </annotation>
  <choice>
    <element ref="gml:DirectionVector"/>
    <element ref="gml:CompassPoint"/>
    <element name="DirectionKeyword" type="gml:CodeType"/>
    <element name="DirectionString" type="gml:StringOrRefType"/>
  </choice>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

The various kinds of direction specifications follow.

### 17.1.2 gml:DirectionVector, gml:DirectionVectorType

Director vectors are specified by providing components of a vector or two angles as follows:

```
<element name="DirectionVector" type="gml:DirectionVectorType"/>

<complexType name="DirectionVectorType">
  <choice>
    <element ref="gml:vector"/>
    <sequence>
      <element name="horizontalAngle" type="gml:AngleType"/>
      <element name="verticalAngle" type="gml:AngleType"/>
    </sequence>
  </choice>
</complexType>
```

The gml:vector element is described in clause 9.1.4.1. This form may appear in an data instance as follows:

```
<gml:direction>
  <gml:DirectionVector>
    <gml:horizontalAngle uom="#degreesEastOfNorth">45.0</gml:horizontalAngle>
    <gml:verticalAngle uom="#degreesDown">0.0</gml:verticalAngle>
  </gml:DirectionVector>
</gml:direction>
```

Angles are specified via gml:AngleType whose content model is defined in clause 16.3.3. This form may appear in an data instance as follows:

```
<gml:direction>
  <gml:DirectionVector>
    <gml:horizontalAngle uom="#degreesEastOfNorth">45.0</gml:horizontalAngle>
    <gml:verticalAngle uom="#degreesDown">0.0</gml:verticalAngle>
  </gml:DirectionVector>
</gml:direction>
```

### 17.1.3 gml:CompassPoint, gml:CompassPointEnumeration

A compass point is specified by a simple enumeration string type. The gml:CompassPoint element is declared in the schema as follows:

```
<element name="CompassPoint" type="gml:CompassPointEnumeration"/>

<simpleType name="CompassPointEnumeration">
  <restriction base="string">
    <enumeration value="N"/>
    <enumeration value="NNE"/>
    <enumeration value="NE"/>
    <enumeration value="ENE"/>
    <enumeration value="E"/>
    <enumeration value="ESE"/>
    <enumeration value="SE"/>
    <enumeration value="SSE"/>
    <enumeration value="S"/>
    <enumeration value="SSW"/>
    <enumeration value="SW"/>
    <enumeration value="WSW"/>
    <enumeration value="W"/>
    <enumeration value="WNW"/>
    <enumeration value="NW"/>
    <enumeration value="NNW"/>
  </restriction>
</simpleType>
```

These directions are necessarily approximate, giving direction with a precision of 22.5°. It is thus generally unnecessary to specify the reference frame, though this may be detailed in the definition of a GML application language.

This form may appear in an data instance as follows:

```
<gml:direction>
  <gml:CompassPoint>WNW</gml:CompassPoint>
</gml:direction>
```

#### 17.1.4 Text Based Directions: `gml:DirectionKeyword`, `gml:DirectionString`

Two elements to contain text-based descriptions of direction are provided.

If the direction is specified using a term from a list, `gml:KeyWord` should be used, and the list indicated using the value of the `codeSpace` attribute. This form may appear in an data instance as follows:

```
<gml:direction>
  <gml:DirectionKeyword codeSpace="http://my.big.org/terms/direction">onshore</gml:DirectionKeyword>
</gml:direction>
```

If the direction is described in prose, `gml:DirectionString` should be used, allowing the value to be included inline or by reference. This form may appear in an data instance as follows:

```
<gml:direction>
  <gml:DirectionString>Towards the lighthouse</gml:DirectionString>
</gml:direction>
```

```
<gml:direction>
  <gml:DirectionString xlink:href="http://my.big.org/logbook/20021127/paragraph6"/>
</gml:direction>
```

## 18 GML schemas – observations

### 18.1 Observations

A GML observation models the act of observing, often with a camera, a person or some form of instrument. An observation feature describes the “metadata” associated with an information capture event, together with a value for the result of the observation. This covers a broad range of cases, from a tourist photo (not the photo but the act of taking the photo), to images acquired by space borne sensors or the measurement of a temperature 5 meters below the surfaces of a Lake. See also Clause 7.9. (measures.xsd).

The basic structures introduced in this schema are intended to serve as the foundation for more comprehensive schemas for scientific, technical and engineering measurement schemas.

### 18.2 Observation schema

Observations are described in the schema, `observations.xsd`. The schema is listed in Annex C. It is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:observation:v3.1.0
```

This schema describes two kinds of observations, `gml:Observation` and `gml:DirectedObservation`.

#### 18.2.1 `gml:Observation`

The `gml:Observation` element is declared in the schema as follows:

```

<element name="Observation" type="gml:ObservationType" substitutionGroup="gml:_Feature"/>

<complexType name="ObservationType">
  <complexContent>
    <extension base="gml:AbstractFeatureType">
      <sequence>
        <element ref="gml:validTime"/>
        <element ref="gml:using" minOccurs="0"/>
        <element ref="gml:target" minOccurs="0"/>
        <element ref="gml:resultOf"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

The content model is a straightforward extension of gml:AbstractFeatureType it automatically has gml:metadataProperty, gml:description, gml:name, gml:location and gml:boundedBy properties.

The gml:validTime element is declared in clause 14.2.2.3. In this context it describes the time of the observation. Note that this can be a time instant or a time period.

### 18.2.2 gml:using

The gml:using property contains or points to a description of a sensor, instrument or procedure used for the observation. It is declared in the schema as follows:

```

<element name="using" type="gml:FeaturePropertyType"/>

```

### 18.2.3 gml:target

The gml:target property contains or points to the specimen, region or station which is the object of the observation. This property element is declared in the schema as follows:

```

<element name="target" type="gml:TargetPropertyType"/>

<element name="subject" type="gml:TargetPropertyType" substitutionGroup="gml:target">

<complexType name="TargetPropertyType">
  <annotation>
    <documentation>Container for an object representing the target or subject of an observation.</documentation>
  </annotation>
  <choice minOccurs="0">
    <element ref="gml:_Feature"/>
    <element ref="gml:_Geometry"/>
  </choice>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

This property is particularly useful for remote observations, such as photographs, where the gml:location property might apply to the location of the camera or the location of the field of view, and thus may be ambiguous.

The subject element is provided as a convenient synonym for target. This is the term commonly used in photography.

### 18.2.4 gml:resultOf

The gml:resultOf property indicates the result of the observation. Following the standard GML property pattern (clause ), the value may be inline, or a reference to a value elsewhere. If the value is inline, it must be a member of the gml:\_Object substitution group. It is declared in the schema as follows:

```
<element name="resultOf" type="gml:AssociationType"/>
```

## 18.3 Examples

### 18.3.1 gml:Observation

Some examples of simple observations are as follows:

```
<gml:Observation>
  <gml:location xlink:href="http://www.environment.org/stations/l456"/>
  <gml:validTime>
    <gml:TimeInstant>
      <gml:timePosition>2002-11-12T09:12:00</gml:timePosition>
    </gml:TimeInstant>
  </gml:validTime>
  <gml:using xlink:href="http://www.my.org/sensors/thermometer4"/>
  <gml:target xlink:href="http://www.environment.org/stations/l456"/>
  <gml:resultOf>
    <gml:Quantity uom="#C">18.4</gml:Quantity>
  </gml:resultOf>
</gml:Observation>
```

```
<gml:Observation>
  <gml:location xlink:href="http://www.tourist.org/lookouts/platform4"/>
  <gml:validTime>
    <gml:TimeInstant>
      <gml:timePosition>2002-11-12T09:12:00</gml:timePosition>
    </gml:TimeInstant>
  </gml:validTime>
  <gml:using xlink:href="http://www.my.org/cameras/leica2"/>
  <gml:subject xlink:href="http://www.tourist.org/sights/mountain3"/>
  <gml:resultOf xlink:href="http://www.my.org/photos/landscape1.jpg"/>
</gml:Observation>
```

```
<gml:Observation>
  <gml:location>
    <gml:LocationString>Home</gml:LocationString>
  </gml:location>
  <gml:validTime>
    <gml:TimeInstant>
      <gml:timePosition>2002-10-25T11:37:25</gml:timePosition>
    </gml:TimeInstant>
  </gml:validTime>
  <gml:subject xlink:href="http://www.people.org/kids/abby"/>
  <gml:resultOf xlink:href="myDaughtersPortrait.jpg"/>
</gml:Observation>
```

### 18.3.2 gml:DirectedObservation

A DirectedObservation is the same as an observation except that it adds an additional direction property. This is the direction in which the observation was acquired. Clearly this applies only to certain types of observations such as visual observations by people, or observations obtained from terrestrial cameras.

```
<element name="DirectedObservation" type="gml:DirectedObservationType"
  substitutionGroup="gml: Observation"/>
```

```
<complexType name="DirectedObservationType">
```

```

<complexContent>
  <extension base="gml:ObservationType">
    <sequence>
      <element ref="gml:direction"/>
    </sequence>
  </extension>
</complexContent>
</complexType>

```

EXAMPLE DirectedObservation:

```

<gml:DirectedObservation>
  <gml:validTime>
    <gml:TimeInstant>
      <gml:timePosition>2002-11-12T09:12:00</gml:timePosition>
    </gml:TimeInstant>
  </gml:validTime>
  <gml:using xlink:href="http://www.my.org/cameras/leica2"/>
  <gml:target xlink:href="http://www.tourist.org/sights/mountain3"/>
  <gml:resultOf xlink:href="http://www.my.org/photos/landscape1.jpg"/>
  <gml:direction>
    <gml:CompassPoint>NW</gml:CompassPoint>
  </gml:direction>
</gml:DirectedObservation>

```

### 18.3.3 gml:DirectedObservationAtDistance

A DirectedObservationAtDistance adds an additional distance property. This is the distance from the observer to the subject of the observation. Clearly this applies only to certain types of observations such as visual observations by people, or observations obtained from terrestrial cameras.

```

<element name="DirectedObservationAtDistance" type="gml:DirectedObservationAtDistanceType"
  substitutionGroup="gml:DirectedObservation"/>

<complexType name="DirectedObservationAtDistanceType">
  <complexContent>
    <extension base="gml:DirectedObservationType">
      <sequence>
        <element name="distance" type="gml:MeasureType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

EXAMPLE DirectedObservationAtDistance:

```

<gml:DirectedObservationAtDistance>
  <gml:validTime>
    <gml:TimeInstant>
      <gml:timePosition>2002-11-12T09:12:00</gml:timePosition>
    </gml:TimeInstant>
  </gml:validTime>
  <gml:using xlink:href="http://www.my.org/cameras/leica2"/>
  <gml:subject xlink:href="http://www.tourist.org/sights/mountain3"/>
  <gml:resultOf xlink:href="http://www.my.org/photos/landscape1.jpg"/>
  <gml:direction>
    <gml:CompassPoint>NW</gml:CompassPoint>
  </gml:direction>
  <gml:distance uom="#m">16500.</gml:distance>
</gml:DirectedObservationAtDistance>

```

## 19 GML schemas – coverages

### 19.1 The coverage model and representations

#### 19.1.1 General Remarks

This clause defines the GML encoding for coverages and is in agreement with the conceptual model outlined in ISO 19123 and in the OGC Abstract Specification, Topic 6.

ISO 19123 provides a definition:

*Coverages support mapping from a spatiotemporal domain to attribute values where attribute types are common to all geographic positions within the spatiotemporal domain. A spatiotemporal domain consists of a collection of direct positions in a coordinate space. Examples of coverages include rasters, triangulated irregular networks, point coverages, and polygon coverages. Coverages are the prevailing data structures in a number of application areas, such as remote sensing, meteorology, and bathymetric, elevation, soil, and vegetation mapping.*

The information describing a coverage is conventionally represented in one of two ways:

- a. As a set of discrete location-value pairs.
- b. As a description of the spatio-temporal domain (multi-geometry, grid) and a description of the set of values from the range, together with a method or rule (which may be implicit) that assigns a value from the range set to each position within the domain.

The first method only applies to domains that are partitioned into discrete components. This representation may be realised in GML as a **homogeneous feature collection** (i.e. all the features have the same set of properties), where the set of locations from the features compose the domain (remember: gml:location may refer to any geometry, not just points), and the set of property values compose the range. The mapping from domain to range is trivial: the properties on each feature are assigned to the location of that feature. For coverages whose domain is composed of a large set of locations this explicit representation may, however, be bulky.

The second method is more flexible in a number of ways.

- a) Since the domain and range are homogeneous sets, there may be efficiencies in the representation of either or both domain and range
- b) The values in the range may be represented in analytic form rather than as discrete explicit values, which is also related to the fact that
- c) When the attribute values vary continuously across the domain, a functional form covering the complete domain is required to be able to provide values of the range at arbitrary locations. The function typically involves interpolation, possibly using a process model.

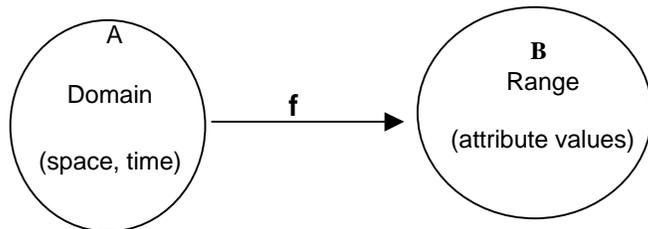

The first representation is typically used during data collection where a set or properties relating to a single location are managed together, or update of a datastore where only a small number of features are manipulated at one time. The second representation is more suitable for analysis, where spatio-temporal patterns and anomalies within a specific property are of interest.

It is the second method, using a functional map over the whole domain, that is the subject of the GML coverage encoding.

#### 19.1.2 Formal description of a coverage

A coverage incorporates a mapping from a spatiotemporal domain to a range set, the latter providing the set in which the attribute values live. The range set can be an arbitrary set including discrete lists, integer or

floating point ranges, and multi-dimensional vector spaces. This conceptual model of a coverage is described in Figure 4.

**Figure 4 – Conceptual Model of a Coverage**

A coverage can be viewed as the graph of the coverage function  $f:A \rightarrow B$ , that is as the set of ordered pairs

$$\{(x, f(x)) \mid \text{where } x \text{ is in } A\}$$

This view is especially applicable to the GML encoding of a coverage. In the case of a discrete coverage, the domain set  $A$  is partitioned into a collection of subsets (typically a disjoint collection)  $A = \cup A_i$  and the function  $f$  is constant on each  $A_i$ . For a spatial domain, the  $A_i$  are geometry elements, hence the coverage can be viewed as a collection of (geometry,value) pairs, where the value is an element of the range set. If the spatial domain  $A$  is a topological space then the coverage can be viewed as a collection of (topology,value) pairs, where the topology element in the pair is a topological  $n$ -chain (in GML terms this is a `gml:TopoPoint`, `gml:TopoCurve`, `gml:TopoSurface` or `gml:TopoSolid`).

### 19.1.3 Coverage in GML

A coverage is implemented as a GML feature. We can thus speak of a “temperature distribution feature”, or a “remotely sensed image feature”, or a “soil distribution feature”.

As is the case for any GML object, a coverage object may also be the value of a property of a feature. For example, the temperature distribution might be a property of a city feature, so a description of the city of Ottawa might be represented in GML as:

```

<abc:City gml:id = "Ottawa">
  <abc:population>500000</abc:population>
  <abc:temperatureDistribution>
    <abc:TemperatureCoverage> ... </abc:TemperatureCoverage>
  </abc:temperatureDistribution>
</abc:City>

```

Diagram annotations: An arrow labeled 'feature' points to the root element <abc:City>. An arrow labeled 'feature (coverage)' points to the <abc:TemperatureCoverage> element.

Coverages in GML 3 are supported by two schemas,

- coverage.xsd
- grids.xsd.

Coverages.xsd provides the basic GML 3 coverage model. Grids.xsd provides grid geometry structures that are used in the description of gridded coverages but which could be employed for other applications.

Future releases of GML will provide other geometries and temporal complexes for use in coverages.

## 19.2 Grids schema

An implicit description of geometry is one in which the items of the geometry do not explicitly appear in the encoding. Instead, a compact notation records a set of parameters, and a set of objects may be generated using a rule with these parameters.

The schema grids.xsd provides some grid geometries that are used in the description of gridded coverages and other applications. The schema is listed in Annex C. It is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:grids:v3.1.0
```

In GML 3 two grid structures are defined, namely `gml:Grid` and `gml:RectifiedGrid`.

### 19.2.1 Unrectified Grid (`gml:Grid`)

The `gml:Grid` element is defined in the schema as follows:

```
<element name="Grid" type="gml:GridType" substitutionGroup="gml:_ImplicitGeometry"/>

<complexType name="GridType">
  <complexContent>
    <extension base="gml:AbstractGeometryType">
      <sequence>
        <element name="limits" type="gml:GridLimitsType"/>
        <element name="axisName" type="string" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The `gml:Grid` implicitly defines an unrectified grid, which is a network composed of two or more sets of equally spaced parallel lines in which the members of each set intersect each other. The region of interest within the grid is given in terms of its **limits**, being the grid coordinates of diagonally opposed corners of a rectangular region. An **axisName** is provided for each of the axes of the grid. The standard `SRSReferenceGroup` is inherited from `gml:AbstractGeometryType`. This includes the **dimension** attribute.

In GML3 the **limits** element contains a single `GridEnvelope`, according to the following schema definitions:

```
<complexType name="GridLimitsType">
  <sequence>
    <element name="GridEnvelope" type="gml:GridEnvelopeType"/>
  </sequence>
</complexType>

<complexType name="GridEnvelopeType">
  <sequence>
    <element name="low" type="gml:integerList"/>
    <element name="high" type="gml:integerList"/>
  </sequence>
</complexType>
```

The low and high elements are each `integerLists`, which are coordinate tuples, the coordinates being measured as offsets from the origin of the grid along each axis, of the diagonally opposing corners of a “rectangular” region of interest.

The following example illustrates a simple `Grid`.

```
<gml:Grid dimension="2">
  <gml:limits>
    <gml:GridEnvelope>
      <gml:low>0 0</gml:low>
      <gml:high>3 3</gml:high>
```

```

</gml:GridEnvelope>
</gml:limits>
<gml:axisName>x</gml:axisName>
<gml:axisName>y</gml:axisName>
</gml:Grid>

```

In this example the Grid has posts (points) at locations (0,0), (0,1),(1,0),(1,1) through to (4,4).

### 19.2.2 Rectified Grid (gml:RectifiedGrid)

A rectified grid is a kind of grid in which the points of the grid have geometric locations. It is defined by specifying the position (in some geometric space) of the grid "origin" and of the vectors that specify the post locations. The RectifiedGrid element is declared in the schema as follows:

```

<element name="RectifiedGrid" type="gml:RectifiedGridType" substitutionGroup="gml:Grid"/>

<complexType name="RectifiedGridType">
  <complexContent>
    <extension base="gml:GridType">
      <sequence>
        <element name="origin" type="gml:PointPropertyType"/>
        <element name="offsetVector" type="gml:VectorType" maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

Note that the grid limits (post indexes) and axis name properties are inherited from the gml:GridType and that the gml:RectifiedGrid adds an origin (contains a gml:Point) and a set of offset vectors specified using gml:VectorType as described in clause 9.1.4.1.

Figure 5 shows the geometry of the RectifiedGrid.

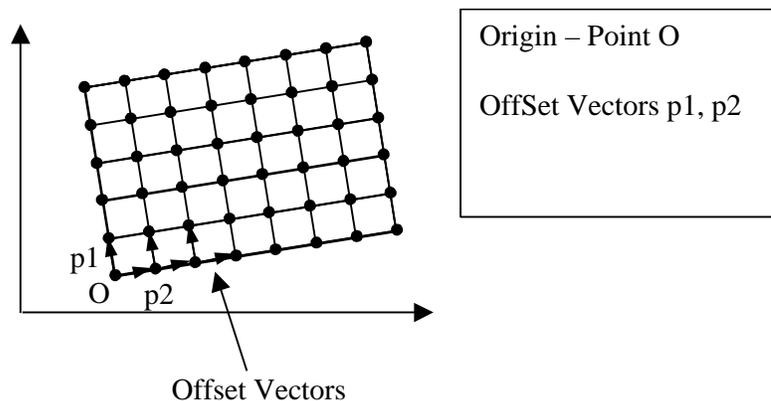

Figure 5 – RectifiedGrid Geometry

An example RectifiedGrid is as follows:

```

<gml:RectifiedGrid dimension="2">
  <gml:limits>
    <gml:GridEnvelope>
      <gml:low>1 1</gml:low>
      <gml:high>3 3</gml:high>
    </gml:GridEnvelope>

```

```

</gml:limits>
<gml:axisName>u</gml:axisName>
<gml:axisName>v</gml:axisName>
<gml:origin>
  <gml:Point gml:id="palindrome" srsName="urn:EPSG:geographicCRS:4327">
    <gml:pos>1.2 3.3 2.1</gml:pos>
  </gml:Point>
</gml:origin>
<gml:offsetVector srsName="urn:EPSG:geographicCRS:4327">1.1 2.2 3.3</gml:offsetVector>
<gml:offsetVector srsName="urn:EPSG:geographicCRS:4327">2.0 1.0 0.0</gml:offsetVector>
</gml:RectifiedGrid>

```

Note that in this example the RectifiedGrid starts at integer offset 1 1 (value of `low` property) relative to the origin as shown in Figure 6.

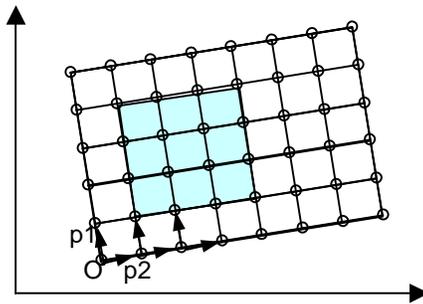

Figure 6 – RectifiedGrid with non-zero low limit

### 19.3 Coverage schema

The coverage.xsd schema is listed in Annex C. It is identified by the following location-independent name (using URN syntax):

```
urn:opengis:specification:gml:schema-xsd:coverage:v3.1.0
```

#### 19.3.1 gml:AbstractCoverageType, gml:\_Coverage

The base type for coverages is `AbstractCoverageType`, defined in the schema as follows:

```

<complexType name="AbstractCoverageType" abstract="true">
  <complexContent>
    <extension base="gml:BoundedFeatureType">
      <sequence>
        <element ref="gml:domainSet"/>
        <element ref="gml:rangeSet"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

NOTE `gml:AbstractCoverageType` is derived by extension from `BoundedFeatureType`, so any coverage whose content model is derived from this type is a GML feature, and the `boundedBy` property is mandatory on all coverages.

The basic elements of a coverage can be seen in this content model: the coverage contains `domainSet` and `rangeSet` properties. The `gml:domainSet` property describes the domain of the coverage and the `rangeSet` property describes the range of the coverage.

The abstract element `gml:_Coverage` is declared as follows:

```
<element name="_Coverage" type="gml:AbstractCoverageType" abstract="true" substitutionGroup="gml:_Feature"/>
```

This element serves as the head of a substitution group which may contain any coverage whose type is derived from `gml:AbstractCoverageType`. It may act as a variable in the definition of content models where it is required to permit any coverage to be valid.

### 19.3.2 `gml:AbstractDiscreteCoverageType`, `gml:_DiscreteCoverage`

A discrete coverage consists of a domain set, range set and optionally a coverage function. The domain set consists of either geometry or temporal objects, finite in number. The range set is comprised of a finite number of attribute values each of which is associated to every direct position within any single spatiotemporal object in the domain. In other words, the range values are constant on each spatiotemporal object in the domain. This coverage function maps each element from the coverage domain to an element in its range. This definition conforms to ISO 19123. The base type for discrete coverages is `AbstractDiscreteCoverageType`, defined in the schema as follows:

```
<complexType name="AbstractDiscreteCoverageType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractCoverageType">
      <sequence>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The `coverageFunction` element describes the mapping “f” as shown in Figure 4.

The abstract element `gml:_DiscreteCoverage` is declared as follows:

```
<element name="_DiscreteCoverage" type="gml:AbstractDiscreteCoverageType" abstract="true"
substitutionGroup="gml:_Coverage"/>
```

This element serves as the head of a substitution group which may contain any discrete coverage whose type is derived from `gml:AbstractDiscreteCoverageType`.

### 19.3.3 `gml:AbstractContinuousCoverageType`, `gml:_ContinuousCoverage`

A continuous coverage as defined in ISO 19123 is a coverage that can return different values for the same feature attribute at different direct positions within a single spatiotemporal object in its spatiotemporal domain. This definition conforms to ISO 19123. The base type for continuous coverages is `AbstractContinuousCoverageType`, defined in the schema as follows:

```
<complexType name="AbstractContinuousCoverageType" abstract="true">
  <annotation>
    <documentation>A continuous coverage as defined in ISO 19123 is a coverage that can return different values
for the same feature attribute at different direct positions within a single spatiotemporal object in its spatiotemporal
domain</documentation>
  </annotation>
  <complexContent>
    <extension base="gml:AbstractCoverageType">
      <sequence>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The coverageFunction element describes the mapping “f” as shown in Figure 4.

The abstract element gml:\_ContinuousCoverage is declared as follows:

```
<element name="_ContinuousCoverage" type="gml:AbstractContinuousCoverageType" abstract="true"
substitutionGroup="gml:_Feature"/>
```

This element serves as the head of a substitution group which may contain any continuous coverage whose type is derived from gml:AbstractContinuousCoverageType.

#### 19.3.4 gml:domainSet, gml:DomainSetType

The Domain Set describes the spatio-temporal region of interest, within which the coverage is defined. Its content model is given by gml:DomainSetType which is defined as follows:

```
<element name="domainSet" type="gml:DomainSetType"/>

<complexType name="DomainSetType">
  <choice minOccurs="0">
    <element ref="gml:_Geometry"/>
    <element ref="gml:_TimeObject"/>
  </choice>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

The value of the domain is thus a choice between a gml:\_Geometry and a gml:\_TimeObject. In the instance these abstract elements will normally be substituted by a geometry complex or temporal complex, to represent spatial coverages and time-series, respectively.

NOTE Spatiotemporal domains are supported if the domain is described using a compound coordinate reference system, one of whose components is temporal. Otherwise, following the ISO 19100 and OGC abstract specifications, GML 3 does not support combined spatial-temporal domains.

The presence of the gml:AssociationAttributeGroup means that domainSet follows the usual GML property model and can use the xlink:href attribute to point to the Domain, as an alternative to describing the domain inline.

#### 19.3.5 gml:rangeSet, gml:RangeSetType

The Range Set contains the values of the coverage (sometimes called the attribute values). Its content model is given by gml:RangeSetType which is defined as follows::

```
<element name="rangeSet" type="gml:RangeSetType"/>

<complexType name="RangeSetType">
  <choice>
    <element ref="gml:ValueArray" maxOccurs="unbounded"/>
    <element ref="gml:_ScalarValueList" maxOccurs="unbounded"/>
    <element ref="gml:DataBlock"/>
    <element ref="gml:File"/>
  </choice>
</complexType>
```

This content model supports a structural description of the Range. The semantic information describing the range set is embedded using a uniform method, as part of the explicit values, or as a template value accompanying the representation using gml:DataBlock and gml:File.

- c) The values from each component (or “band”) in the range may be encoded within a gml:ValueArray element or a concrete member of the gml:\_ScalarValueList substitution group (e.g. gml:CategoryList, gml:QuantityList - see clause 16.4). Use of these elements satisfies the value-type homogeneity requirement

### 19.3.6 gml:DataBlock

gml:DataBlock describes the Range as a block of text encoded values similar to a Common Separated Value (CSV) representation. The content model is as follows:

```
<element name="DataBlock" type="gml:DataBlockType"/>

<complexType name="DataBlockType">
  <sequence>
    <element ref="gml:rangeParameters"/>
    <choice>
      <element ref="gml:tupleList"/>
      <element ref="gml:doubleOrNullTupleList"/>
    </choice>
  </sequence>
</complexType>
```

The range set parameterization is described by the property gml:rangeParameters.

### 19.3.7 gml:rangeParameters

The gml:rangeParameters property is declared as follows:

```
<element name="rangeParameters" type="gml:RangeParametersType"/>

<complexType name="RangeParametersType">
  <sequence>
    <element ref="gml:_Value" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

gml:RangeParameterType is a framework for the description of the range parameters each of which is a gml:\_Value, as described in clause 16.4. Specific range parameters are defined through the creation of a GML Application Schema that provides elements that are substitutable for gml:\_Value.

### 19.3.8 gml:tupleList

The gml:tupleList property is declared as follows:

```
<element name="tupleList" type="gml:CoordinatesType"/>
```

gml:CoordinatesType is described in clause 9.1.3.3. It consists of a list of coordinate tuples, with each coordinate tuple separated by the ts or tuple separator (by default this is whitespace), and each coordinate in the tuple by the cs or coordinate separator (by default this is a comma).

The gml:tupleList encoding is effectively “band-interleaved”. An example of a set of pairs of temperature and pressure observations might be recorded in a gml:DataBlock as follows:

```
<gml:DataBlock>
  <gml:rangeParameters>
    <gml:CompositeValue>
      <gml:valueComponents>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">template</Temperature>
        <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
      </gml:valueComponents>
    </gml:CompositeValue>
  </gml:rangeParameters>
  <gml:tupleList>3,101.2 5,101.3 7,101.4 11,101.5 13,101.6 17,101.7 19,101.7 23,101.8 29,101.9 31,102.0
37,102.1 41,102.2 43,102.3 47,102.4 53,102.5 59,102.6</gml:tupleList>
</gml:DataBlock>
```

where Temperature and Pressure are elements defined in a local application schema, using gml:MeasureOrNullListType.

### 19.3.9 gml:doubleOrNullTupleList

The gml:doubleOrNullTupleList property is declared as follows:

```
<element name="doubleOrNullTupleList" type="gml:doubleOrNullList"/>
```

gml:doubleOrNullList is described in clause 7.3.4.1. It consists of a list of doubleOrNull values, each separated by a whitespace. The doubleOrNull values are grouped into tuples where the dimension of each tuple in the list is equal to the number of range parameters.

An example of the use of gml:doubleOrNullTupleList to record the same set of pairs of temperature and pressure observations given in the gml:DataBlock example above is as follows:

```
<gml:DataBlock>
  <gml:rangeParameters>
    <gml:CompositeValue>
      <gml:valueComponents>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">template</Temperature>
        <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
      </gml:valueComponents>
    </gml:CompositeValue>
  </gml:rangeParameters>
  <gml:doubleOrNullTupleList>3 101.2 5 101.3 7 101.4 11 101.5 13 101.6 17 101.7 19 101.7 23 101.8 29
  101.9 31 102.0 37 102.1 41 102.2 43 102.3 47 102.4 53 102.5 59 102.6</gml:doubleOrNullTupleList>
</gml:DataBlock>
```

### 19.3.10 gml:File, gml:FileType

For efficiency reasons, GML 3 also provides a means of encoding the range set in an arbitrary external encoding, such as a binary file. This encoding may be “well-known” but this is not required. This mode uses the gml:File element, which is declared as follows:

```
<element name="File" type="gml:FileType"/>

<complexType name="FileType">
  <sequence>
    <element ref="gml:rangeParameters"/>
    <element name="fileName" type="anyURI"/>
    <element name="fileStructure" type="gml:FileValueType"/>
    <element name="mimeType" type="anyURI" minOccurs="0"/>
    <element name="compression" type="anyURI" minOccurs="0"/>
  </sequence>
</complexType>
```

In this version of the coverage encoding, the values of the coverage (attribute values in the Range set) are transmitted in a binary file that is referenced from the XML structure described by gml:FileType. The binary file is referenced by the fileName property that is an anyURI. This means that the binary file can be located remotely from the referencing GML instance. This can support, for example, both an http reference and a SOAP attachment.

The compression property points to a definition of a compression algorithm through an anyURI. This may be a retrievable, computable definition or simply a reference to an unambiguous name for the compression method.

The mime type property points to a definition of the file mime type.

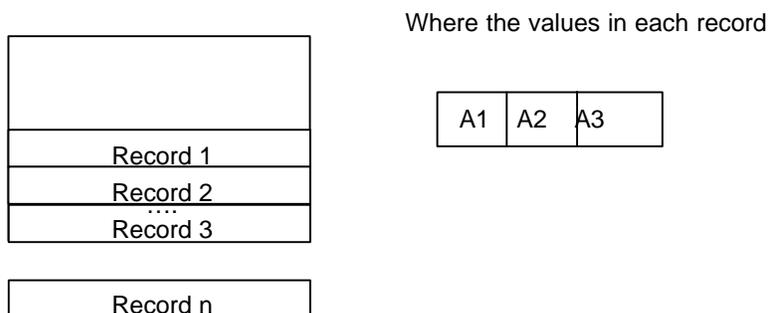

The fileStructure property is defined by the gml:FileValueType. This is simple enumerated type restriction on string. The only value supported in GML 3 is "Record Interleaved". Additional values may be supported in future releases of GML. Note further that all values shall be enclosed in a single file. Multi-file structures for values are not supported in GML 3.

The semantics of the Range set is described as above using gml:rangeParameters.

EXAMPLE Binary File Encoding:

```
<gml:File>
  <gml:rangeParameters>
    <gml:CompositeValue>
      <gml:valueComponents>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">template</Temperature>
        <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
      </gml:valueComponents>
    </gml:CompositeValue>
  </gml:rangeParameters>
  <gml:fileName>http://www.somedata.org/temp_pressure.dat</gml:fileName>
  <gml:fileStructure>Record Interleaved</gml:fileStructure>
</gml:File>
```

The referenced file structure shall be as follows:

**Figure 7 – File Record Structure or Coverage File**

Note that if any compression algorithm is applied, the structure above applies only to the pre-compression or post-decompression structure of the file.

Note that the fields within a record match the valueComponents of the CompositeValue in document order.

### 19.3.11 gml:coverageFunction, gml:CoverageFunctionType

This clause describes the Coverage Function (gml:coverageFunction) property, that is, the mapping “f” (see Figure 4) from the domain to the range of the coverage. The content model for the coverage function is given by:

```
<element name="coverageFunction" type="gml:CoverageFunctionType"/>
<complexType name="CoverageFunctionType">
  <choice>
    <element ref="gml:MappingRule"/>
    <element ref="gml:GridFunction"/>
  </choice>
</complexType>
```

Note that the value of the CoverageFunction is one of gml:MappingRule and gml:GridFunction.

### 19.3.12 gml:MappingRule

gml:MappingRule provides a formal (e.g. MathML) or informal (e.g. free text) description of the coverage function, per:

```
<element name="MappingRule" type="gml:StringOrRefType"/>
```

The mapping rule may be defined as an in-line string or via a remote reference through xlink:href.

If no rule name is specified, the default is ‘Linear’ with respect to members of the domain in document order.

### 19.3.13 gml:GridFunction, gml:GridFunctionType

gml:GridFunction provides an explicit mapping rule for grid geometries, i.e. the domain shall be a geometry of type grid. It describes the mapping of grid posts (discrete point grid coverage) or grid cells (discrete surface coverage) to the values in the RangeSet. The content model is as follows:

```
<element name="GridFunction" type="gml:GridFunctionType"/>
```

```

<complexType name="GridFunctionType">
  <sequence>
    <element name="sequenceRule" type="gml:SequenceRuleType" minOccurs="0"/>
    <element name="startPoint" type="gml:integerList" minOccurs="0">
  </sequence>
</complexType>

```

The startPoint is the index position of a point in the grid that is mapped to the first point in the Range Set (this is also the index position of the first grid post). *If the startPoint is omitted the startPoint is assumed to be equal to the value of gml:low in the gml:Grid geometry.* Subsequent points in the mapping are determined by the value of the sequenceRule.

### 19.3.14 gml:sequenceRule, gml:SequenceRuleType, gml:SequenceRuleNames

The sequenceRule is described by the content model:

```

<complexType name="SequenceRuleType">
  <simpleContent>
    <extension base="gml:SequenceRuleNames">
      <attribute name="order" type="gml:IncrementOrder" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

```

The SequenceRuleType is derived from the gml:SequenceRuleNames through the addition of an order attribute. The gml:SequenceRuleNames is an enumerated type defined as:

```

<simpleType name="SequenceRuleNames">
  <restriction base="string">
    <enumeration value="Linear"/>
    <enumeration value="Boustrophedonic"/>
    <enumeration value="Cantor-diagonal"/>
    <enumeration value="Spiral"/>
    <enumeration value="Morton"/>
    <enumeration value="Hilbert"/>
  </restriction>
</simpleType>

```

These rule names are defined in ISO 19123.

*If no rule name is specified the default is "Linear".*

The order attribute is also defined in ISO 19123 and its value is determined by the content model:

```

<simpleType name="IncrementOrder">
  <annotation>
    <documentation> </documentation>
  </annotation>
  <restriction base="string">
    <enumeration value="+x+y"/>
    <enumeration value="+y+x"/>
    <enumeration value="+x-y"/>
    <enumeration value="-x-y"/>
  </restriction>
</simpleType>

```

The enumeration value here indicates the incrementing order to be used on the first 2 axes, i.e. "+x-y" means that the points on the first axis are to be traversed from lowest to highest and the points on the second axis are to be traversed from highest to lowest. The points on all other axes (if any) beyond the first 2 are assumed to increment from lowest to highest.

If the order attribute is omitted it is assumed to have the value “+x+y”.

If the coverageFunction property is omitted for Gridded Coverages (included RectifiedGridded Coverages) the startPoint is assumed to be the value of the gml:low property in the gml:Grid geometry, and the sequenceRule is assumed to be linear and the order attribute is assumed to be “+x+y”. This is best illustrated by a simple example as follows:

```
<AverageTempPressure
  xmlns="http://www.opengis.net/app" xmlns:gml="http://www.opengis.net/gml"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.opengis.net/app ./CoverageExamples.xsd">
  <gml:domainSet>
    <gml:Grid dimension="2">
      <gml:limits>
        <gml:GridEnvelope>
          <gml:low>0 0</gml:low>
          <gml:high>4 4</gml:high>
        </gml:GridEnvelope>
      </gml:limits>
      <gml:axisName>x</gml:axisName>
      <gml:axisName>y</gml:axisName>
    </gml:Grid>
  </gml:domainSet>
  <gml:rangeSet>
    <gml:DataBlock>
      <gml:rangeParameters>
        <gml:CompositeValue>
          <gml:valueComponents>
            <Temperature uom="urn:x-si:v1999:uom:degreesC">template</Temperature>
            <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
          </gml:valueComponents>
        </gml:CompositeValue>
      </gml:rangeParameters>
      <gml:tupleList>3,101.2 5,101.3 7,101.4 11,101.5 13,101.6 17,101.7 19,101.7 23,101.8 29,101.9 31,102.0
37,102.1 41,102.2 43,102.3 47,102.4 53,102.5 59,102.6</gml:tupleList>
    </gml:DataBlock>
  </gml:rangeSet>
</AverageTempPressure>
```

Since no coverageFunction is specified the function is assumed to be that of linear scanning with “+x+y” order starting at the location (0 0). If we look at the DataBlock we see that we have the following mapping.

**Table 5 – Data block example**

Grid Location	Data Value
0 0	3,101.2
1 0	5,101.3
2 0	7,101.4
3 0	11,101.5
0 1	13,101.6
1 1	17,101.7
2 1	19,101.7
3 1	23,101.8
0 2	29,101.9
1 2	31,102.0
2 2	37,102.1
3 2	41,102.2

0 3	43,102.3
1 3	47,102.4
2 3	53,102.5
3 3	59,102.6

### 19.3.15 Specific Coverage Types in GML 3.1

GML 3 supports all of the discrete coverage types defined in ISO 19123.

The supported types are derived from `gml:AbstractDiscreteCoverageType` and include:

- `MultiPointCoverage`
- `MultiCurveCoverage`
- `MultiSurfaceCoverage`
- `MultiSolidCoverage`
- Gridded Coverage (discrete point coverage)
- Rectified Grid Coverage (discrete point coverage)

Additional specific continuous coverage types can be anticipated in future releases of GML. Users can also construct their own coverage types by deriving from `gml:AbstractDiscreteCoverageType`, `AbstractContinuousCoverageType` or by derivation from the specific concrete coverage types above.

Note that the same Range Set encodings apply for each of the different discrete coverage types as the latter are specified by the geometry type of the domain.

### 19.3.16 MultiPoint Coverage

In a `MultiPoint Coverage` the domain set is a `gml:MultiPoint`, that is a collection of arbitrarily distributed geometric points. The content model for a `MultiPoint Coverage` is as follows:

```
<complexType name="MultiPointCoverageType">
  <complexContent>
    <restriction base="gml:AbstractCoverageType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:multiPointDomain"/>
        <element ref="gml:rangeSet"/>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

Note that this is defined by restriction on `gml:AbstractCoverageType`. Note that the restriction replaces the generic `gml:domainSet` by the specific `gml:multiPointDomain` whose value is a `gml:MultiPoint`.

```
<complexType name="MultiPointDomainType">
  <complexContent>
    <restriction base="gml:DomainSetType">
      <sequence minOccurs="0">
```

```

    <element ref="gml:MultiPoint"/>
  </sequence>
</restriction>
</complexContent>
</complexType>

```

Note that in a MultiPoint Coverage the mapping from the domain to the range is straightforward.

- a) For DataBlock encodings the points of the MultiPoint are mapped in document order to the tuples of the DataBlock.
- b) For CompositeValue encodings the points of the MultiPoint are mapped to the members of the CompositeValue in document order.
- c) For File encodings the points of the MultiPoint are mapped to the records of the File in sequential order.

EXAMPLE MultiPoint Coverage (uses Value encoding):

```

<AverageTempPressure
  xmlns="http://www.opengis.net/app"
  xmlns:gml="http://www.opengis.net/gml"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.opengis.net/app CoverageExamples.xsd">
  <gml:domainSet>
    <gml:MultiPoint srsName="urn:EPSG:geographicCRS:4326">
      <gml:pointMember>
        <gml:Point>
          <gml:pos>1 1</gml:pos>
        </gml:Point>
      </gml:pointMember>
      <gml:pointMember>
        <gml:Point>
          <gml:pos>2 2</gml:pos>
        </gml:Point>
      </gml:pointMember>
      <gml:pointMember>
        <gml:Point>
          <gml:pos>3 3</gml:pos>
        </gml:Point>
      </gml:pointMember>
      <gml:pointMember>
        <gml:Point>
          <gml:pos>4 4</gml:pos>
        </gml:Point>
      </gml:pointMember>
    </gml:MultiPoint>
  </gml:domainSet>
  <gml:rangeSet>
    <gml:ValueArray>
      <gml:valueComponents>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">3</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">5</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">7</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">11</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">13</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">17</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">19</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">23</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">29</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">31</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">37</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">41</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">43</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">47</Temperature>
      </gml:valueComponents>
    </gml:ValueArray>
  </gml:rangeSet>
</AverageTempPressure>

```

```

        <Temperature uom="urn:x-si:v1999:uom:degreesC">53</Temperature>
        <Temperature uom="urn:x-si:v1999:uom:degreesC">59</Temperature>
    </gml:valueComponents>
</gml:ValueArray>
</gml:rangeSet>
</AverageTempPressure>

```

### 19.3.17 MultiCurve Coverage

In a multi-curve coverage the domain is partitioned into a collection of curve elements comprising a gml:MultiCurve. The coverage function then maps each curve element in the collection to a value in the Range Set. The content model for the MultiCurve coverage is as follows:

```

<complexType name="MultiCurveCoverageType">
  <complexContent>
    <restriction base="gml:AbstractCoverageType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:multiCurveDomain"/>
        <element ref="gml:rangeSet"/>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>

```

Note that the domainSet is now a multiCurveDomain with value a gml:MultiCurve.

The coverage function provides a mapping from the elements of the MultiCurve to the values in the Range Set.

In the DataBlock encoding, the members of the MultiCurve (value of the multiCurveDomain) are mapped to the tuples in the DataBlock in document order.

In the File encoding, the members of the MultiCurve are mapped to the records in the File in document order.

In the CompositeValue encoding the members of the MultiCurve are mapped to the members of the CompositeValue in document order.

EXAMPLE MultiCurve Coverage (uses DataBlock encoding):

```

<AverageTempPressure
  xmlns="http://www.opengis.net/app"
  xmlns:gml="http://www.opengis.net/gml"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.opengis.net/app CoverageExamples.xsd">
  <gml:domainSet>
    <gml:MultiCurve srsName="urn:EPSG:geographicCRS:4326">
      <gml:curveMember>
        <gml:LineString>
          <gml:posList dimension="2">1.1 1.1 2.2 2.2</gml:posList>
        </gml:LineString>
      </gml:curveMember>
      <gml:curveMember>
        <gml:LineString>
          <gml:posList dimension="2">2.2 2.2 3.3 3.3</gml:posList>
        </gml:LineString>
      </gml:curveMember>
      <gml:curveMember>
        <gml:LineString>

```

```

        <gml:posList dimension="2">3.3 3.3 4.4 4.4</gml:posList>
      </gml:LineString>
    </gml:curveMember>
  </gml:curveMember>
  <gml:LineString>
    <gml:posList dimension="2">4.4 4.4 5.5 5.5</gml:posList>
  </gml:LineString>
</gml:curveMember>
</gml:MultiCurve>
</gml:domainSet>
<gml:rangeSet>
  <gml:DataBlock>
    <gml:rangeParameters>
      <gml:CompositeValue>
        <gml:valueComponents>
          <Temperature uom="urn:x-si:v1999:uom:degreesC">template</Temperature>
          <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
        </gml:valueComponents>
      </gml:CompositeValue>
    </gml:rangeParameters>
    <gml:doubleOrNullTupleList>3 101.2 5 101.3 7 101.4 11 101.5</gml:doubleOrNullTupleList>
  </gml:DataBlock>
</gml:rangeSet>
</AverageTempPressure>

```

### 19.3.18 MultiSurface Coverage

In a multi-surface coverage the domain is partitioned into a collection of surface elements comprising a `gml:MultiSurface`. The coverage function then maps each surface element in the collection to a value in the Range Set. The content model for the MultiSurface coverage is as follows:

```

<complexType name="MultiSurfaceCoverageType">
  <complexContent>
    <restriction base="gml:AbstractCoverageType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:multiSurfaceDomain"/>
        <element ref="gml:rangeSet"/>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>

```

Note that the domainSet is now a multiSurfaceDomain with value a `gml:MultiSurface`.

The coverage function provides a mapping from the elements of the MultiSurface to the values in the Range Set.

In the DataBlock encoding, the members of the MultiSurface (value of the multiSurfaceDomain) are mapped to the tuples in the DataBlock in document order.

In the File encoding, the members of the MultiSurface are mapped to the records in the File in document order.

In the CompositeValue encoding the members of the MultiSurface are mapped to the members of the CompositeValue in document order.

EXAMPLE      MultiSurface Coverage (uses File encoding for values):

```

<SoilData xmlns="http://www.opengis.net/app" xmlns:gml="http://www.opengis.net/gml"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:schemaLocation="http://www.opengis.net/app
./CoverageExamples.xsd">
  <gml:domainSet>
    <gml:MultiSurface srsName="urn:EPSG:geographicCRS:4326">
      <gml:surfaceMember>
        <gml:Polygon gid="p1">
          <gml:exterior>
            <gml:LinearRing>
              <gml:posList dimension="3">1. 2. 3.</gml:posList>
            </gml:LinearRing>
          </gml:exterior>
        </gml:Polygon>
      </gml:surfaceMember>
      <gml:surfaceMember>
        <gml:Polygon gid="p6">
          <gml:exterior>
            <gml:LinearRing>
              <gml:posList dimension="3">4. 5. 6.</gml:posList>
            </gml:LinearRing>
          </gml:exterior>
        </gml:Polygon>
      </gml:surfaceMember>
      <gml:surfaceMember>
        <gml:Polygon gid="p11">
          <gml:exterior>
            <gml:LinearRing>
              <gml:posList dimension="3">7. 8. 9.</gml:posList>
            </gml:LinearRing>
          </gml:exterior>
        </gml:Polygon>
      </gml:surfaceMember>
      <gml:surfaceMember>
        <gml:Polygon gid="p16">
          <gml:exterior>
            <gml:LinearRing>
              <gml:posList dimension="3">10. 11. 12.</gml:posList>
            </gml:LinearRing>
          </gml:exterior>
        </gml:Polygon>
      </gml:surfaceMember>
    </gml:MultiSurface>
  </gml:domainSet>
  <gml:rangeSet>
    <gml:File>
      <gml:rangeParameters>
        <gml:CompositeValue>
          <gml:valueComponent>
            <SoilType codeSpace="http://my.big.org/classifications/soils">template</SoilType>
          </gml:valueComponent>
          <gml:valueComponent>
            <SoilMoisture uom="http://my.big.org/units/percent">template</SoilMoisture>
          </gml:valueComponent>
        </gml:CompositeValue>
      </gml:rangeParameters>
      <gml:fileName>soil.dat</gml:fileName>
      <gml:fileStructure>Record Interleaved</gml:fileStructure>
    </gml:File>
  </gml:rangeSet>

```

### 19.3.19 MultiSolid Coverage

In a multi-solid coverage the domain is partitioned into a collection of solid elements comprising a `gml:MultiSolid`. The coverage function then maps each solid element in the collection to a value in the Range Set. The content model for the MultiSolid coverage is as follows:

```
<complexType name="MultiSolidCoverageType">
  <complexContent>
    <restriction base="gml:AbstractCoverageType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:multiSolidDomain"/>
        <element ref="gml:rangeSet"/>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

Note that the domainSet is now a multiSolidDomain with value a `gml:MultiSolid`.

The coverage function provides a mapping from the elements of the MultiSolid to the values in the Range Set.

In the DataBlock encoding, the members of the MultiSolid (value of the multiSolidDomain) are mapped to the tuples in the DataBlock in document order.

In the File encoding, the members of the MultiSolid are mapped to the records in the File in document order.

In the CompositeValue encoding the members of the MultiSolid are mapped to the members of the CompositeValue in document order.

### 19.3.20 Gridded Coverage

A gridded coverage is a discrete point coverage in which the domain set is a geometric grid of points as shown in Figure 8.

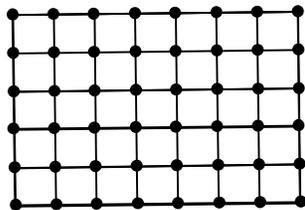

Figure 8 – Gridded Coverage domain is a grid of points

The content model for the gridded coverage is as follows:

```
<element name="GridCoverage" type="gml:GridCoverageType" substitutionGroup="gml:_Coverage"/>

<complexType name="GridCoverageType">
  <complexContent>
    <restriction base="gml:AbstractCoverageType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:gridDomain"/>
        <element ref="gml:rangeSet"/>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

```

    </restriction>
  </complexContent>
</complexType>

```

Note that this is the same as the MultiPoint coverage except that we have a gml:gridDomain property to describe the domain.

The gml:gridDomain is defined as:

```

<complexType name="GridDomainType">
  <complexContent>
    <restriction base="gml:DomainSetType">
      <choice minOccurs="0">
        <element ref="gml:Grid"/>
      </choice>
    </restriction>
  </complexContent>
</complexType>

```

The gml:Grid is defined in the grids.xsd discussed in Clause 19.2. Note that the simple gridded coverage is not geometrically referenced and hence no geometric positions are assignable to the points in the grid. Such geometric positioning is introduced in the RectifiedGrid Coverage discussed in Clause 19.2.2.

EXAMPLE      Grid Coverage (uses File encoding for values):

```

<AverageTempPressure>
  <gml:gridDomain>
    <gml:Grid dimension="2">
      <gml:limits>
        <gml:GridEnvelope>
          <gml:low>0 0</gml:low>
          <gml:high>4 4</gml:high>
        </gml:GridEnvelope>
      </gml:limits>
      <gml:axisName>x</gml:axisName>
      <gml:axisName>y</gml:axisName>
    </gml:Grid>
  </gml:gridDomain>
  <gml:rangeSet>
    <gml:File>
      <gml:rangeParameters>
        <gml:CompositeValue>
          <gml:valueComponents>
            <Temperature uom="urn:x-si:v1999:uom:degreesC">template</Temperature>
            <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
          </gml:valueComponents>
        </gml:CompositeValue>
      </gml:rangeParameters>
      <gml:fileName>http://www.somedata.org/temp_pressure.dat</gml:fileName>
      <gml:fileStructure>Record Interleaved</gml:fileStructure>
    </gml:File>
  </gml:rangeSet>
</AverageTempPressure>

```

### 19.3.21 RectifiedGrid Coverage

The rectified grid coverage is a discrete point coverage based on a rectified grid.

The rectified grid coverage is similar to the grid coverage of Clause 19.2.2 except that the points of the grid are geometrically referenced. The rectified grid coverage has a domain that is a RectifiedGrid geometry as defined in the grids.xsd of Clause 19.2.

The content model for gml:RectifiedGridCoverage is as follows:

```
<complexType name="RectifiedGridCoverageType">
  <complexContent>
    <restriction base="gml:AbstractCoverageType">
      <sequence>
        <group ref="gml:StandardObjectProperties"/>
        <element ref="gml:boundedBy"/>
        <element ref="gml:rectifiedGridDomain"/>
        <element ref="gml:rangeSet"/>
        <element ref="gml:coverageFunction" minOccurs="0"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

Note that the coverage domain is described by gml:rectifiedGridDomain.

```
<complexType name="RectifiedGridDomainType">
  <complexContent>
    <restriction base="gml:DomainSetType">
      <choice minOccurs="0">
        <element ref="gml:RectifiedGrid"/>
      </choice>
    </restriction>
  </complexContent>
</complexType>
```

where the gml:RectifiedGrid geometry is defined in grids.xsd discussed in Clause 19.2.

EXAMPLE RectifiedGrid Coverage (using DataBlock):

```
<AveragePressure xmlns="http://www.opengis.net/app" xmlns:gml="http://www.opengis.net/gml"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:schemaLocation="http://www.opengis.net/app
./CoverageExamples.xsd">
  <gml:rectifiedGridDomain>
    <gml:RectifiedGrid dimension="2">
      <gml:limits>
        <gml:GridEnvelope>
          <gml:low>1 1</gml:low>
          <gml:high>4 4</gml:high>
        </gml:GridEnvelope>
      </gml:limits>
      <gml:axisName>u</gml:axisName>
      <gml:axisName>v</gml:axisName>
      <gml:origin>
        <gml:Point gml:id="palindrome" srsName="urn:EPSG:geographicCRS:4327">
          <gml:pos>1.2 3.3 2.1</gml:pos>
        </gml:Point>
      </gml:origin>
      <gml:offsetVector srsName="urn:EPSG:geographicCRS:4327">1.1 2.2 3.3</gml:offsetVector>
      <gml:offsetVector srsName="urn:EPSG:geographicCRS:4327">2.0 1.0 0.0</gml:offsetVector>
    </gml:RectifiedGrid>
  </gml:rectifiedGridDomain>
  <gml:rangeSet>
    <gml:DataBlock>
      <gml:rangeParameters>
        <gml:CompositeValue>
          <gml:valueComponents>
            <Pressure uom="urn:x-si:v1999:uom:kPa">template</Pressure>
          </gml:valueComponents>
        </gml:CompositeValue>
      </gml:rangeParameters>
```

```
<gml:doubleOrNullTupleList>101.2 101.3 101.4 101.5 101.6 101.7 101.7 101.8 101.9 102.0 102.1 102.2 102.3
102.4 102.5 102.6</gml:doubleOrNullTupleList>
</gml:DataBlock>
</gml:rangeSet>
</AveragePressure>
```

## 20 GML schemas – default styling

### 20.1 General concepts

One of the requirements in developing of GML is the strict separation of data and presentation. Therefore none of the GML data description constructs have built-in capability to describe the styling information. Rather, the default styling mechanism was created as a separate model that can be “plugged-in” to a GML data set. An example of the use of such pluggable mechanism is data styling information persistence.

The term “default” signifies very relaxed relation to other parts of the GML model. The style information that is assigned to a data set may be used for styling but may also be completely ignored.

The default style schema is directly related to the rest of the GML schemas only in that it imports some very basic constructs from it. None of the other GML schemas depend on the styling one. It also depends on W3C Synchronized Multimedia Integration Language (SMIL) schemas.

The relation of the default style information and GML data instances is achieved through the `gml:defaultStyle` property defined in `defaultStyle.xsd` schema. The property may be assigned to the instance by defining such a relationship in application schema. Since GML is feature-based encoding, GML default style always applies to a feature, features or feature collections.

The UML containment diagram of the styling model is shown in Figure 9.

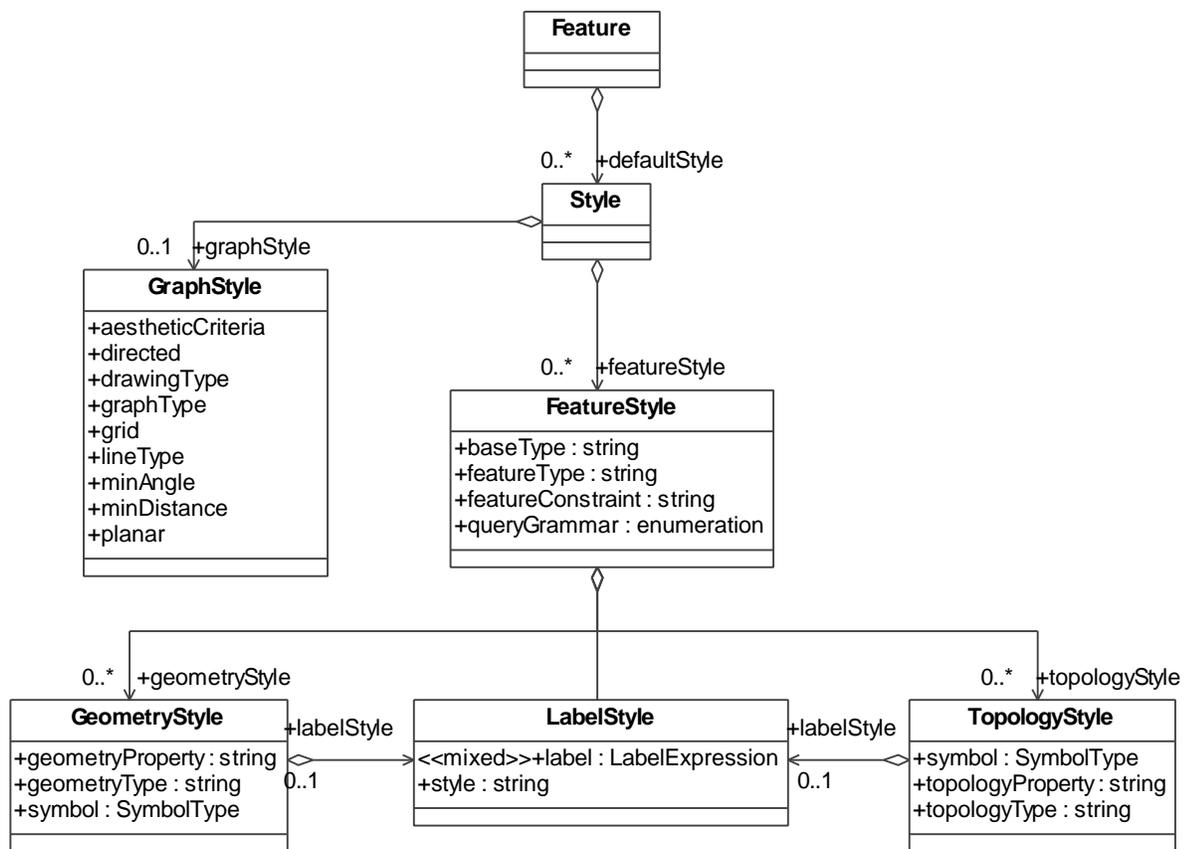

Figure 9 – The GML default styling containment model diagram

The UML inheritance diagram of the styling model is shown in Figure 10.

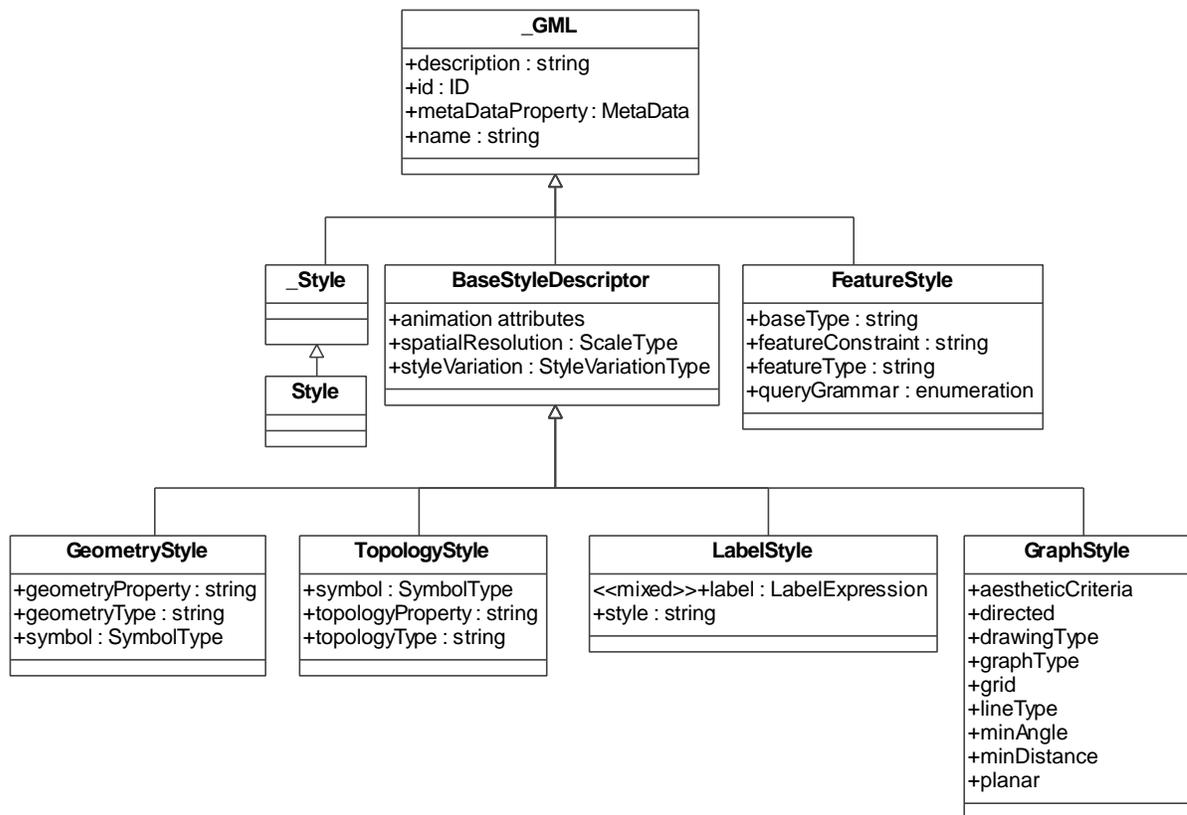

Figure 10 – The GML default styling inheritance model diagram

## 20.2 Top-level styling elements

The connection between a GML data set and a styling description is minimal. It is established through only one property, the `gml:defaultStyle`. The value of this property, the `gml:Style` object, contains all styling descriptions..

### 20.2.1 `gml:defaultStyle`

The `gml:defaultStyle` property is a property defined as a global element in GML namespace and thus can be assigned to any feature or a feature collection defined in an application schema. The definition of the property is shown in the following listing:

```

<element name="defaultStyle" type="gml:DefaultStylePropertyType"/>

<complexType name="DefaultStylePropertyType">
  <sequence>
    <element ref="gml:_Style" minOccurs="0"/>
  </sequence>
  <attribute name="about" type="anyURI" use="optional"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

```

To include this property in a feature users shall do so via the feature application schema. This is achieved by including it in a definition in an application schema. Following is an example of an exp:Road feature definition that includes the gml:defaultStyle property.

```
<element name="Road" type="exp:RoadType" substitutionGroup="gml:_Feature"/>

<complexType name="RoadType">
  <complexContent>
    <extension base="gml:AbstractFeatureType">
      <sequence>
        <element ref="gml:centerLineOf"/>
        <element ref="gml:defaultStyle"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The gml:AssociationAttributeGroup on the property contains the simple XLink attribute group from xlink.xsd schema and the the remoteSchema attribute. Attributes from xlink.xsd schema allow a user to specify the value of the property remotely instead of inline. The remoteSchema attribute may be used to specify the schema of the property's value.

The about attribute on the property allows us to assign the style to an arbitrary feature or feature collection regardless of the style's location. The meaning of the attribute is that "The style is about (applies to) feature or features that can be found at the URI that is the attribute value".

## 20.2.2 gml:Style

The gml:Style object is the default concrete value of the gml:defaultStyle property. It is the top-level styling object that encapsulates all other, partial style descriptions. It's definition is presented in the following listing:

```
<element name="Style" type="gml:StyleType" substitutionGroup="gml:_Style"/>

<complexType name="StyleType">
  <complexContent>
    <extension base="gml:AbstractStyleType">
      <sequence>
        <element ref="gml:featureStyle" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:graphStyle" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The gml:StyleType which is the content model of the gml:Style object extends the gml:AbstractStyleType. This base abstract type serves as an abstract base for extensibility purposes, i.e. creating custom style objects, and it does not add any new content to the gml:AbstractGMLType from which it derives. This can be seen in the listing below:

```
<element name="_Style" type="gml:AbstractStyleType" abstract="true" substitutionGroup="gml:_GML"/>

<complexType name="AbstractStyleType" abstract="true">
  <complexContent>
    <extension base="gml:AbstractGMLType"/>
  </complexContent>
</complexType>
```

However, it is not assumed that creating custom style objects will be usual practice since gml:Style object provides rich capabilities for describing styles. In case of using this mechanism, usual GML rules have to be observed:

- d) The content model of the custom style object has to derive from gml:AbstractStyleType.

- e) The custom style object has to be substitutable for abstract `gml:_Style`.

The definition of the `gml:Style` object presented previously in the text is itself a proper example of using the extensibility mechanism and it shows how these rules are implemented in the schema.

The function of the styling elements in the `gml:Style` object, namely `gml:FeatureStyle` and `gml:GraphStyle` is to describe styles for two aspects of GML data: individual features and topology graphs that consist of collections of features. Note that elements that describe styles for particular aspects of features, namely, feature style, graph style, geometry style, topology style and label style are often called style descriptors.

## 20.3 Feature style

### 20.3.1 `gml:FeatureStyle`

Feature style descriptor is assigned to the `gml:Style` element using `gml:featureStyle` property. It allows, like other GML properties, to specify the value inline or remotely. For that purpose it has the attributes from the `gml:AssociationAttributeGroup` as well as the `about` attribute. Its schema is shown in the following listing:

```
<element name="featureStyle" type="gml:FeatureStylePropertyType"/>

<complexType name="FeatureStylePropertyType">
  <sequence>
    <element ref="gml:FeatureStyle" minOccurs="0"/>
  </sequence>
  <attribute name="about" type="anyURI" use="optional"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

Its value is `gml:FeatureStyle` – the feature style descriptor. Feature style descriptor describes the styling information for a set of feature instances. The set is defined by the selection mechanisms that are part of this style descriptor. The style applies to each feature in the set independently - no relations that might exist among features in the set are significant. (The opposite case is graph style where the style applies to a set of features as a whole). The definition of the feature style descriptor is shown in the following listing:

```
<element name="FeatureStyle" type="gml:FeatureStyleType" substitutionGroup="gml:_GML"/>

<complexType name="FeatureStyleType">
  <complexContent>
    <extension base="gml:AbstractGMLType">
      <sequence>
        <element name="featureConstraint" type="string" minOccurs="0"/>
        <element ref="gml:geometryStyle" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:topologyStyle" minOccurs="0" maxOccurs="unbounded"/>
        <element ref="gml:labelStyle" minOccurs="0"/>
      </sequence>
      <attribute name="featureType" type="string" use="optional"/>
      <attribute name="baseType" type="string" use="optional"/>
      <attribute name="queryGrammar" type="gml:QueryGrammarEnumeration"/>
    </extension>
  </complexContent>
</complexType>
```

Feature instances to which the style applies are selected using one of the attributes `featureType` or `baseType` and `gml:featureConstraint` element. These two attributes shall be used exclusively, with or without the `gml:featureConstraint` element.

### 20.3.2 `featureType`

The simplest and most common way of relating features and styles is by using this attribute. It's value will be the declared name of a feature, instances of which we want to style. For example, if the value is `exp:Road`, the

gml:FeatureStyle object will simply apply to all Road features. The value of this attribute is always the name of the element from the application schema that declares the feature.

### 20.3.3 baseType

Another way of selecting the feature instances to which the style applies is to specify, as the value of this attribute, the name of the base type from which feature or features derive. This is always the name of an XMLSchema complex type. Any complex type from the derivation chain can be used; the style applies to any feature instance that ultimately derives from it. If we use, for example, gml:AbstractFeatureType as the attribute's value, the style applies to all feature instances in a data set.

### 20.3.4 featureConstraint

This property is used to further constrain the feature instance set to which the style applies. It is optional and its value is an XPath expression. If the property does not exist, the style applies to all feature instances selected by featureType or baseType attribute.

### 20.3.5 queryGrammar

The value of this property which is defined as an enumeration specifies the grammar that is used in the content of the gml:featureConstraint element. The enumeration allows for three values: Xpath, Xquery and other.

Styling features means styling a particular aspect or aspects of a feature. We can style feature geometry, topology or display arbitrary text string. Feature style contains three style descriptors for respective purposes: gml:GeometryStyle, gml:TopologyStyle and gml:LabelStyle.

## 20.4 Geometry Style

The value of the gml:geometryStyle property is gml:GeometryStyle descriptor which describes the style for one geometry of a feature. Any number of geometry style descriptors can be assigned to one feature style. This is usually required for features with multiple geometry properties.

Geometry style property and descriptor are defined as follows:

```
<element name="geometryStyle" type="gml:GeometryStylePropertyType"/>
```

```
<complexType name="GeometryStylePropertyType">
  <sequence>
    <element ref="gml:GeometryStyle" minOccurs="0"/>
  </sequence>
  <attribute name="about" type="anyURI" use="optional"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

```
<element name="GeometryStyle" type="gml:GeometryStyleType" substitutionGroup="gml:_GML"/>
```

```
<complexType name="GeometryStyleType">
  <complexContent>
    <extension base="gml:BaseStyleDescriptorType">
      <sequence>
        <choice>
          <element ref="gml:symbol"/>
          <element name="style" type="string">
            <annotation>
              <appinfo>deprecated</appinfo>
              <documentation>
                Deprecated in GML version 3.1.0. Use symbol with inline content instead.
              </documentation>
            </annotation>
          </element>
        </choice>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

        </choice>
        <element ref="gml:labelStyle" minOccurs="0"/>
    </sequence>
    <attribute name="geometryProperty" type="string"/>
    <attribute name="geometryType" type="string"/>
</extension>
</complexContent>
</complexType>

```

The gml:geometryStyle is defined in the same manner as other GML properties which allow for referencing the value remotely or inline.

The geometryProperty attribute on the gml:GeometryStyle specifies the name of the geometry property of a feature to which this geometry style descriptor applies. It is necessary to specify the geometry type using geometryType attribute as well since the application schema of the geometry property may allow different geometries as it's value.

Element gml:symbol is described in the section 20.7.2.

## 20.5 Topology Style

The value of the gml:topologyStyle property is gml:TopologyStyle descriptor which describes the style for one topology property. Similarly to the gml:Geometry style, a feature can have multiple topology properties, thus multiple topology style descriptors can be specified within one feature style.

The definition of topology style property and descriptor are presented in the following listing:

```

<element name="topologyStyle" type="gml:TopologyStylePropertyType"/>

<complexType name="TopologyStylePropertyType">
    <sequence>
        <element ref="gml:TopologyStyle" minOccurs="0"/>
    </sequence>
    <attribute name="about" type="anyURI" use="optional"/>
    <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="TopologyStyle" type="gml:TopologyStyleType" substitutionGroup="gml:_GML"/>

<complexType name="TopologyStyleType">
    <complexContent>
        <extension base="gml:BaseStyleDescriptorType">
            <sequence>
                <choice>
                    <element ref="gml:symbol"/>
                    <element name="style" type="string">
                        <annotation>
                            <appinfo>deprecated</appinfo>
                            <documentation>
                                Deprecated in GML version 3.1.0. Use symbol with inline content instead.
                            </documentation>
                        </annotation>
                    </element>
                </choice>
                <element ref="gml:labelStyle" minOccurs="0"/>
            </sequence>
            <attribute name="topologyProperty" type="string"/>
            <attribute name="topologyType" type="string"/>
        </extension>
    </complexContent>
</complexType>

```

The `gml:topologyStyle` property is defined in the same manner as other GML properties which allow for referencing the value remotely or inline.

The `topologyProperty` attribute on the `gml:TopologyStyle` descriptor specifies the name of the topology property of a feature to which this topology style descriptor applies. It is necessary to specify the topology type using `topologyType` attribute as well since the application schema of the topology property may allow different topologies as its value.

Element `gml:symbol` is described in the section 20.7.2.

## 20.6 Label Style

The value of the `gml:labelStyle` property is `gml:LabelStyle` descriptor which describes the style for the text that is to be displayed along with the graphical representation of a feature. The content of the label is not necessarily defined in the GML data set. More precisely, the content can be static text specified in the style itself and the text from the GML data set.

Label style has two elements: `gml:style` that specifies the style and `gml:label` that is used to compose the label content. The definitions of the `gml:labelStyle` property and `gml:LabelStyle` descriptor are given in the following listing:

```
<element name="labelStyle" type="gml:LabelStylePropertyType"/>
<complexType name="LabelStylePropertyType">
  <sequence>
    <element ref="gml:LabelStyle" minOccurs="0"/>
  </sequence>
  <attribute name="about" type="anyURI" use="optional"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
<element name="LabelStyle" type="gml:LabelStyleType" substitutionGroup="gml:_GML"/>
<complexType name="LabelStyleType">
  <complexContent>
    <extension base="gml:BaseStyleDescriptorType">
      <sequence>
        <element name="style" type="string"/>
        <element name="label" type="gml:LabelType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

The `gml:labelStyle` property is defined in the same manner as other GML properties which allow for referencing the value remotely or inline.

The `gml:style` element is used to specify the style of the rendered text. The type of this element is `xsd:string` and the CSS2 styling expressions grammar is used to express graphic properties. The following example shows the use of the `gml:style` element in the geometry style context.

```
<gml:FeatureStyle featureType="exp:City">
  <gml:GeometryStyle>
    <gml:style>fill:blue;stroke:white</gml:style>
  </gml:GeometryStyle>
</gml:FeatureStyle>
```

As noted, the `gml:label` property on the `gml:LabelStyle` descriptor holds the textual content that can be composed of static text and the text extracted from the GML data. The definition of the `gml:label` element that is used to extract the data is given below:

```

<complexType name="LabelType" mixed="true">
  <sequence>
    <element name="LabelExpression" type="string" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <attribute ref="gml:transform" use="optional"/>
</complexType>

```

The content model is mixed to allow both text content and unbounded number of gml:LabelExpression elements. The value of gml:LabelExpression element is an XPath expression that selects the value of some property of the feature.

For example consider this GML data fragment and corresponding gml:label style:

```

<exp:City>
  <gml:name>Belgrade</gml:name>
  <exp:size>1,700,000</exp:size>
  <gml:extentOf>
    ...
  </gml:extentOf>
</exp:City>

<gml:FeatureStyle featureType="exp:City">
  <gml:LabelStyle>
    <gml:style>font-family:Verdana;font-size:18;fill:red</gml:style>
    <gml:label>
      City:
      <gml:LabelExpression>//City/name</gml:LabelExpression>
      , Size:
      <gml:LabelExpression>//City/size</gml:LabelExpression>
    </gml:label>
  </gml:LabelStyle>
</gml:FeatureStyle>

```

This label style will result in the following text being displayed:

City: Belgrade, Size: 1,700,000

## 20.7 Common styling elements

### 20.7.1 Overview

Some common styling elements are used in multiple style descriptors. The gml:symbol element is used by geometry and topology style descriptors. The spatialResolution, styleVariation and animation attributes are declared in gml:BaseStyleDescriptorType, and inherited by geometry, topology, label and graph style descriptors.

### 20.7.2 gml:symbol

The symbol element specifies a graphical symbol used to render a geometry or a topology. A symbol is a description of graphical attributes of a graphical object without a particular, implicit meaning. It can be a description of a line, circle, polygon or more complex drawing. Using the symbol element, we can specify a particular symbol in two ways:

- a) Remote: Just like any other remote property, the symbol property has the gml:AssociationAttributeGroup attributes that allow for specifying a link pointing to a remote object.
- b) Inline: The value of the gml:symbol property is the any specifier. This allows for specifying an arbitrary grammar for the symbol.

This element has two additional attributes: `symbolType` and `transform`. The `symbolType` attribute is enumeration and can take one of three values: `svg`, `xpath` or `other`. Applications will rely on the value of this attribute to decide how to interpret the symbol.

The `transform` attribute allows us to specify a transformation expression that will be applied to the symbol in the rendering phase. Its type is `xsd:string` and the value is specified in the SVG specification (`transform` attribute).

### 20.7.3 `gml:styleVariation`

The function of the `styleVariation` element is manifold:

- a) Styling labels: Label style does not have a symbol associated with it since the content is not graphical but is given textually. Using this property we can specify its style attributes.
- b) Styling symbol variations: One symbol is often used in different cases with slight modifications. It would be cumbersome to create and manage large number of virtually identical symbols; it is easier to create and use only one symbol and express minor differences in its style using this property.
- c) Parametrized styles: Parametrized styles are styles whose attributes depend on some property of the feature being styled. For example, a city might be styled differently depending on its population. The `styleVariation` property allows for specifying such dependencies.

The definition of this element's content is:

```
<complexType name="StyleVariationType">
  <simpleContent>
    <extension base="string">
      <attribute name="styleProperty" type="string" use="required"/>
      <attribute name="featurePropertyRange" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>
```

It has two attributes: `styleProperty` and `featurePropertyRange`. The value of the `styleProperty` is an SVG styling attribute name, such as "stroke", "fill", etc. It specifies what attribute of the style the property sets or overrides. The value of the `styleVariation` element is the value of the styling attribute specified by the `styleProperty`. The value may be a constant expression or an XPath expression.

The `featurePropertyRange` attribute defines the subset of features to which the variation applies. Its value is an XPath expression.

The following example shows two variations of the symbol style for a City feature. The feature is styled using a circle symbol. The radius of the circle depends on the population of the city, and is also calculated differently depending whether the population of the city is greater or less than 2 million.

```
<gml:FeatureStyle featureType="exp:City">
  <gml:GeometryStyle>
    <gml:styleVariation
      styleProperty="r"
      featurePropertyRange="population >= 2000000">population div 1000000</gml:styleVariation>
    <gml:styleVariation
      styleProperty="r"
      featurePropertyRange="population < 2000000">population div 1000000</gml:styleVariation>
    <gml:symbol xlink:href="http://www.opengis.org/symbols/City.xml#City"/>
  </gml:GeometryStyle>
</gml:FeatureStyle>
```

## 20.7.4 gml:spatialResolution

The value of the spatialResolution element is defined in the measures.xsd GML schema. The value is derived from the measure type, which is xsd:double type with uom (units of measure) attribute. In GML styling, the meaning of this element is based on the corresponding definition in ISO 19115 (Metadata), where it is defined as a factor that provides a general understanding of the density of spatial data in the data set. Other than this informal definition, GML does not specify the exact use of this attribute. Application developers can use spatialResolution in different ways. For example, it can be used as a map scale denominator (1:50,000, 1:25000, etc.). Applications can also use its value to determine how to draw features in different scales. For example, a city and its features are typically drawn in more details on a large scale map, and perhaps only as a single symbol on a small scale map. Or a coastline can be drawn in detail on a large scale map, while a small scale map application can omit some coordinates for better performance.

## 20.7.5 animation

Animation attributes are used to describe the animation behaviour of the geometry, topology, label or graph. These attributes are defined in the W3C SMIL specification (SMIL 2.0 BasicAnimation Elements):

**Table 6 Attributes used for Animation**

Attribute	Used For
animate	Generic attribute animation
animateMotion	Moving an element along the path
animateColor	Animating colour attributes
set	Setting the value of an attribute for a specified duration

## 20.8 Graph Style

The gml:graphStyle property of the gml:FeatureStyle descriptor has as its value the gml:GraphStyle descriptor which describes style attributes of a graph formed by a set of features. The definitions of the graph style property and descriptor are shown in the following listing:

```
<element name="graphStyle" type="gml:GraphStylePropertyType"/>

<complexType name="GraphStylePropertyType">
  <sequence>
    <element ref="gml:GraphStyle" minOccurs="0"/>
  </sequence>
  <attribute name="about" type="anyURI" use="optional"/>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<element name="GraphStyle" type="gml:GraphStyleType" substitutionGroup="gml:_GML"/>

<complexType name="GraphStyleType">
  <complexContent>
    <extension base="gml:BaseStyleDescriptorType">
      <sequence>
        <element name="planar" type="boolean" minOccurs="0"/>
        <element name="directed" type="boolean" minOccurs="0"/>
        <element name="grid" type="boolean" minOccurs="0"/>
        <element name="minDistance" type="double" minOccurs="0"/>
        <element name="minAngle" type="double" minOccurs="0"/>
        <element name="graphType" type="gml:GraphTypeType" minOccurs="0"/>
        <element name="drawingType" type="gml:DrawingTypeType" minOccurs="0"/>
        <element name="lineType" type="gml:LineTypeType" minOccurs="0"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

```

        <element name="aestheticCriteria" type="gml:AesheticCriteriaType" minOccurs="0"
maxOccurs="unbounded"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

The gml :graphStyle property is defined in the same manner as other GML properties which allow for referencing the value remotely or inline.

Graph style descriptor describes the style for a graph as a whole, not for individual graph elements. It inherits from the base content model common styling properties described in the section 20.2.

This descriptor adds to the base content model a group of properties specific to graph styling – they describe the graph in terms of it’s specific characteristics. The properties are described in the following table.

**Table 7 Elements used in graph styling**

Element	Type	Use
Planar	xsd:boolean	If true, the graph edges do not cross (planar graph); if false they may cross
directed	xsd:boolean	If true the graph is directed; if false it is not directed
Grid	xsd:boolean	If true, the coordinates of vertices, crossings and bends have integer values, otherwise they may have decimal values
minDistance	xsd:double	A recommendation for the minimum distance between vertices and non-incident edges
minAngle	xsd:double	A recommendation for the minimum angle between consecutive incident edges (angular resolution)
graphType	xsd:enumeration	The type of the graph. The value may be TREE or BICONNECTED
drawingType	xsd:enumeration	the type of the drawing with respect to the orthogonality of edges. The value may be POLYLINE or ORTHOGONAL
lineType	xsd:enumeration	Determines whether there will be any bent edges. The value may be STRAIGHT or BENT
aestheticCriteria	xsd:enumeration	A recommendation for the general outline of the graph according to a particular aesthetic criteria. The value may be one of the following: MIN_CROSSINGS, MIN_AREA, MIN_BENDS, MAX_BENDS, UNIFORM_BENDS, MIN_SLOPES, MIN_EDGE_LENGTH, MAX_EDGE_LENGTH, UNIFORM_EDGE_LENGTH, MAX_ANGULAR_RESOLUTION, MIN_ASPECT_RATIO or MAX_SYMMETRIES

## 21 Modularisation and Dependencies

The base schemas for GML described above have been modularised so that application schemas that do not need the complete set of GML definitions may import only the topical subsets of GML that are required. For example, a GML version 2 application schema migrating to GML version 3 without adding any new definitions could continue to import feature.xsd. It would not import or require parsing of the new GML version 3 definitions for coordinate reference systems, topology, coverages, dynamic features, default styles, and observations. However, it would import and require parsing of all of the basic types that have been added in GML version 3.

The modularisation of GML creates the dependencies among the GML base schemas shown in Figure 11 below. A dashed arrow in the figure indicates that the schema at the tail of the arrow depends upon the schema at the head of the arrow. A dependency may occur where one schema <include>s another schema in the “gml” namespace. For example, feature.xsd <include>s geometryBasic2d.xsd. A dependency may also occur where one schema <import>s another schema for a namespace other than “gml”. For example, gmlBase.xsd <import>s xlink.xsd from the “xlink” namespace.

There are now seven schemas in GML upon which no other GML schemas depend. These top level schemas are the roots of partially overlapping hierarchies of GML schemas:

- observation.xsd
- dynamicFeature.xsd
- coverage.xsd
- topology.xsd
- defaultStyle.xsd
- coordinateReferenceSystems.xsd
- temporalReferenceSystems.xsd

An application schema that needs definitions from more than one of these GML topical subset schema hierarchies can <import> gml.xsd and get all of the GML definitions. Or it can contain multiple <import>s for just the appropriate gml schema documents, thereby excluding unwanted GML type definitions. However, as specified in [XMLSchema-2] clause 4.2.3, “it is open to applications to ignore all but the first <import> for a given namespace”.

To work around this problem, an application schema writer may create a custom top-level GML schema by copying the <schema> element from gml.xsd, and <including> just the appropriate gml schema documents. This custom top-level GML schema in the “http://www.opengis.net/gml” namespace named “gml” is then <import>ed into the application schema, which uses its own application-specific namespace. For example, an application schema for features with topology could <import> a custom top-level GML schema that <include>s just feature.xsd and topology.xsd, thereby importing 17 fewer schemas than would have been imported using gml.xsd.

However, when an application schema will be used in a processing environment that lacks CPU, memory and/or I/O bandwidth, for example, in a mobile hand-held device, an absolutely minimal <import> of GML definitions is often desired. The custom top-level GML schema approach described above might bring in a unacceptably large number of unwanted definitions from each GML schema <include>d in the custom top-level GML schema. The solution is to create a single GML subset schema that contains exactly the required GML type and element definitions. However, creating such a GML subset schema by hand using a text or XML editor to cut and paste definitions is a tedious and error-prone process because it involves analyzing type definition dependencies across the many GML schema documents. An automated approach is recommended instead. An informative sample implementation of a GML schema subset tool is included in Annex F. Subset schemas, however they are produced, are Profiles of GML as described in Clause 22.

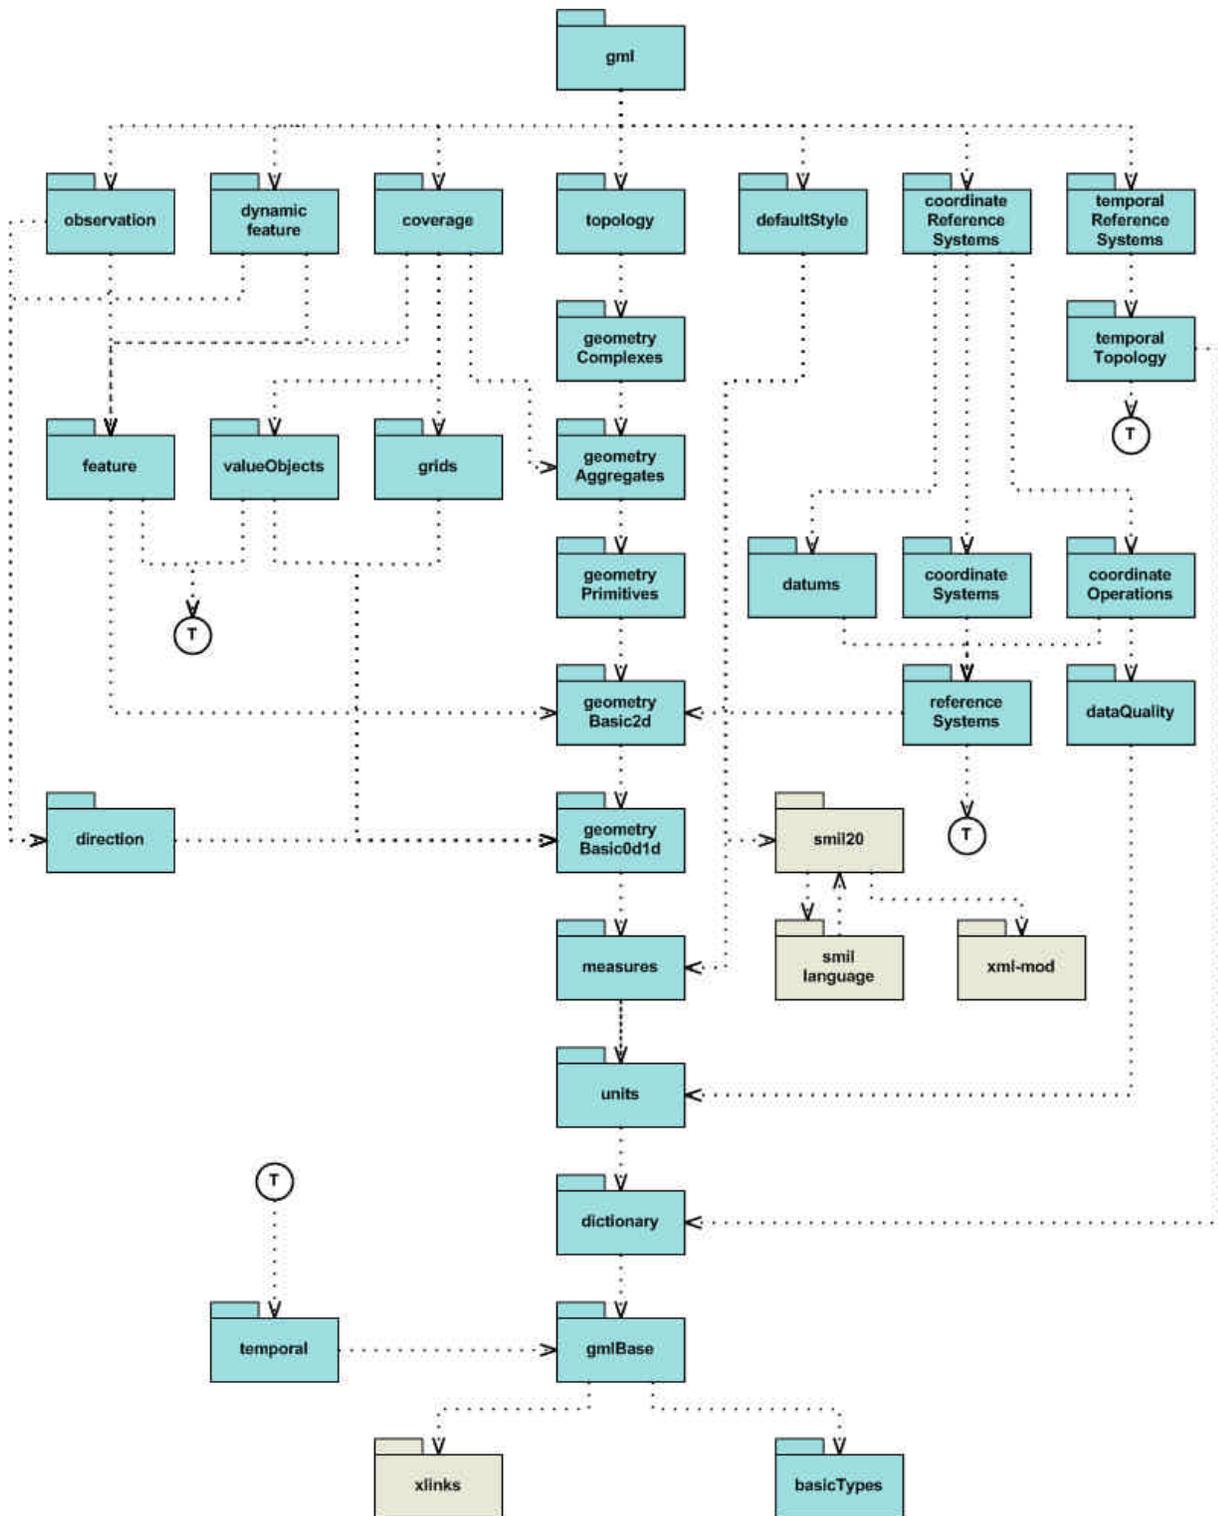

Figure 11 — Schema Dependencies

## 22 Profiles

### 22.1 Profiles of GML and application schemas

GML is a complex specification that is richly expressive. In general, an application need not exploit the entire specification, but may employ a subset of constructs corresponding to specific relevant requirements.

Quoting from technical report “ISO/IEC TR 10000-1:1998 Information technology - Framework and taxonomy of International Standardized Profiles - Part 1: General principles and documentation framework”, we use this definition of a profile:

**Profile:** *A set of one or more base standards and/or [profiles], and, where applicable, the identification of chosen classes [(types, attributes and elements)], conforming subsets, options and parameters of those base standards, or [profiles] necessary to accomplish a particular function.*

Of course, this was defined for an OSI architecture model, so we must translate ‘class’ to ‘types, attributes and elements’ to apply this definition to XML Schema. There are several ways to implements this, and GML profiles uses a “copy and delete” approach. To create a profile, a developer might copy the applicable schema files from GML and simply delete any global types, elements and local optional particles that she does not need for her application schema.

### 22.2 Definition of Profile

A profile of GML can be defined to enhance interoperability and to curtail ambiguity by allowing only a specific subset of GML. Application schemas can then conform to such a profile in order to take advantage of any interoperability or performance advantages that it offers in comparison with a complete GML. Such profiles can be defined for application schemas that are included in other OGC specifications.

There are cases where reduced functionality is acceptable, or where processing requirements compel use of a logical subset of GML. For example, applications that do not need to handle XLink attributes in any form can adhere to a specific profile that excludes them; the constraint in this case would be to not use links. Other cases might include defining constraints on the level of nesting allowed inside tags (i.e. tree depth), or only allowing features with homogeneous properties as members of a feature collection. In many cases, such constraints can be enforced via new schemas; others may be enforced through procedural agreements within an information community.

### 22.3 Relation to application schema

A profile can be the beginning of an application schema. For example, a location based service profile can limit the types of geometry to that used in LBS applications, and the LBS application schema can then add a “PointCircle,” “PointEllipse” and “PointArc” elements to accommodate the LIF “CIRCLE,” “ELLIPSE” and “ARC” elements, which are used to describe error estimates of mobile device location.

The building of such application schemas is thus a two-part process. The profile acts as a restriction of GML to produce types and elements consistent with the complete GML 3 but potentially lacking in some optional particles. The application schema then uses these types as a common base, and uses them in new types and elements by extensions or inclusion.

GML 3 — selection & restriction → GML profile — extension & inclusion → application schema

### 22.4 Rules for elements and types in a profile

Global profiled elements in a GML profile shall:

- a) Share the same name (and namespace) of a parent element in GML.
- b) Include all mandatory particles (subelements and attributes) of the parent element in GML.

- c) Include no particle that is not in the parent element in GML.
- d) Have the same default values for attributes as the parent element in GML.
- e) Have a parallel substitution group hierarchy for named elements in both schemas.

Global types in a GML profile shall:

- a) Share the same name (and namespace) of a parent type in GML.
- b) Include all mandatory particles (subelements and attributes) of the parent type in GML.
- c) Include no particle that is not in the parent type in GML.
- d) Have the same default values for attributes as the parent type in GML.
- e) Have a parallel derivation tree for named types in both schemas.

Instance documents of a profile shall be valid against the full GML schema.

Using the “copy and delete” metaphor described above, our mythic developer can:

- a) Delete global element and global types.
- b) Delete optional subelements from any types or elements
- c) Make optional subelements or attributes mandatory in any type or element (if a default value exist, it shall be eliminated or the schema validation will report an error — default values are only valid for optional particles)
- d) Restrict cardinality of any particle.

None of the above will affect the validity of a document that is designed against the profile, but tested against the full GML schema. Our mythic developer **cannot**:

- a) Delete mandatory subelements from any types or elements.
- b) Make mandatory particles optional.
- c) Relax cardinality restrictions of any particle.
- d) Add or change a default or fixed value.

Item d) is a bit subtler than the others are. Documents valid under the profile would still be valid under the full GML schema, but the interpretation of those documents would change. For example, if a profile specified a default coordinate reference system to be UTM, and the full schema specified a WGS84 geodesic (latitude, longitude) as the default CRS, then the interpretation of the file would change when moving from the profile to the full schema.

## 22.5 Recommendations for application schemas using GML profiles

In order that the profile within an application schema can be later extended to include other profiled GML elements, the following recommendations are made:

- a) Global elements that are not in a GML profile but are in an application schema using a GML profile should not have the same name as any element in the GML schemas.

- b) Global types that are not in a GML profile but are in an application schema using a GML profile should not have the same name as any type in the GML schemas.

If a type or element in an application schema is found to be of universal use, then the above conventions will aid the application schema from migrating that type or element from its own namespace to that of GML.

The following recommendations are made simply as a bookkeeping convenience to those trying to understand the role of the profile in the application schema:

- a) Profiled elements and types should be included in a file structure that parallels that of GML. The exact naming convention of the parallelism is left to the application schema author.
- b) A reference to the appropriate GML schema file should be made in a comment near the beginning of the file.
- c) The profile should use the GML namespace (<http://www.opengis.net/gml>)

## 22.6 Summary of Rules for GML profiles

In summary, the rules for a profile:

- a) A profile of GML is a logical restriction of a subset of GML.
- b) A profile shall not change the name, definition, or data type of mandatory GML elements or attributes.
- c) The relevant schema or schemas that define a profile shall use in the core 'gml' namespace <http://www.opengis.net/gml>.
- d) An application schema may extend and use types from the profile, but shall do so in its own namespace, and not use <http://www.opengis.net/gml>.

The functional test of these rules is:

In any instance document for an application schema using a GML profile will be valid against the same application schema if the GML profile is replaced by the complete GML schema. Further, the interpretation of that document would be the same regardless of which of the two schemas were used.

## 23 Rules for Application Schemes

### 23.1 GML Documents

An XML document contains a single XML element as its root. Several document types are permitted using GML, including:

- A Feature
- A Feature Collection
- A Coverage (Coverages are Features so is a Feature Collection)
- A Dictionary, including a Coordinate Reference System Dictionary or Units of Measure Dictionary
- A Topological Complex

The standard methods for XML documents based on W3C XML Schema, provide that the XML namespaces used in a document are declared as attributes within the document, and the location of schema documents that provide the source components for each namespace may be indicated.

For a GML document, the source of the components describing the primary components within the document is a GML Application Schema. Both the document type and the associated application schema are described in this clause.

## 23.2 GML Application Schemas

A GML Application Schema is an XML Schema, conforming to the rules outlined in this clause, that describes one or more types of geographic objects, components of geographic objects, or meta data, including dictionaries and definitions, used in the definition of geographic objects.. A GML Application Schema defines a vocabulary for a particular domain of discourse by defining and describing the terms of that vocabulary (see ISO 19109) as follows.

An application schema directly uses concrete GML elements and attributes whose names and content models accurately represent components of the vocabulary it defines, e.g. gml:location, gml:name, gml:description, gml:Observation, gml:id, gml:Dictionary, gml:FeatureCollection.

An application schema declares new elements and attributes in its own namespace using GML types when the vocabulary it defines needs to include different names for the same content models to distinguish their semantic roles. The element declared in the application schema will be in a different namespace, and may be used in an instance document. E.g. gml:EnvelopeType may be used unmodified as the content model for an element xml:Interval.

An application schema derives new types in its own namespace by extension of GML types when the vocabulary it defines needs to include components with additional, domain-specific properties.

An application schema derives new types in its own namespace by restriction of GML types when the vocabulary it defines needs to include more specialized versions of GML types that restrict the cardinality or type of their properties.

An application schema declares new elements and attributes in its own namespace using types it has defined to give vocabulary-specific names to their content models.

An application schema declares new elements that are assigned to a substitution group whose head is an abstract or concrete GML element. The element declared in the application schema may then appear in instance documents in place of the substitution group head and be conformant to the content model that refers to the substitution group head. Note that in order to be a valid member of a substitution group, the type of the element shall be validly derived from the type of the element which is the head of the substitution group. All abstract elements in the GML schemas are only useful acting as the heads of substitution groups. E.g. gml:\_GML, gml:\_Feature, \_gml:\_Geometry, gml:\_TimeObject

All GML Application Schemas are constructed, using the general rules of this clause and its sub clauses, from one or more of the core GML schemas defined in Clauses 7 to 20.

In GML 2, GML Application Schemas were restricted to the development of vocabularies of geographic features and all application schemas were based on the feature.xsd.

In GML 3, this concept is extended and several different types of application schemas can be constructed including Feature Schemas, Geometry Schemas, Topology Schemas, Temporal Schemas, Coordinate System Schemas, Coverage Schemas, Observation Schemas, and Value Schemas. Additional rules for the construction of schemas are discussed in the following clauses.

GML also allows the derivation of many other kinds of elements such as new units of measure, new geometry properties and new geometries. While these elements can be packaged into separate schemas they are viewed as subordinate to the schema categories of this clause. Any conformant GML application schema shall be one of the schema types listed below, or be a schema document that complies to the rules from the

respective schema clause. It is thus permissible to create a GML application schema that defines Features, Coverages and Values, so long as this schema satisfies the rules of Clauses 23.3, 23.8 and 23.9.

### 23.2.1 Target Namespace

An application schema shall declare a target namespace. This is the namespace in which the terms for objects and properties of the vocabulary defined by the application schema “live”. This shall not be the GML namespace (<http://www.opengis.net/gml>). It is conventional for the namespace identifier to be a URL controlled by the application schema author’s organization. A target namespace is declared in an application schema using the targetNamespace attribute of the schema element from XML Schema.

An application schema may be comprised of multiple schema documents that all declare the same target namespace. Note that a top level schema document in such a modularised application schema should directly or indirectly include the others to avoid the XML application processing limitations discussed in section 21 Modularisation and Dependencies above.

### 23.2.2 Import GML Schema

An application schema shall import all of the components from GML 3 that it directly or indirectly uses to define its vocabulary. The required import of a specific gml schema in clauses 23.\*.2 below may be provided indirectly via the import of another schema in the namespace for gml that includes the required gml schema. For example, the import of gml.xsd would satisfy any of these schema import requirements. In addition, the required import of a gml schema may be provided by the import of an equivalent subset schema as described in clause 22, or by the import of an equivalent schema from a GML profile that defines the complex type of the document root element. These are all equivalent schemas with respect to satisfying the schema import requirements. For example:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../gml.xsd"/>
```

Note that the <import> element specifies that the components described in gml.xsd are associated with the GML namespace <http://www.opengis.net/gml>. This namespace identifier shall match the target namespace specified in the schema being imported in order to ensure XML Schema validity.

The path (schemaLocation) to the imported GML schema can be to a local copy of the document, or may be a URI reference to a copy of the schema document in some remote repository, such as the repository <http://schemas.opengis.net/> on the OGC web site.

### 23.2.3 Object Type Derivation

An object type declared by an application schema shall not violate any XML Schema derivation restrictions imposed by a “final” attribute on its base GML type.

An object type defined by an application schema shall derive directly from the most specialized GML object type that can serve as the base for its content model while preserving semantic consistency and increasing type specialization.

### 23.2.4 Elements Representing Objects

An application schema shall declare a global element for any object type that is to serve as the root element in a GML instance document.

### 23.2.5 Property Type Derivation

A property type defined by an application schema to contain or reference a single GML object may be derived from gml:AssociationType, or may follow the pattern of gml:AssociationType.

A property type defined by an application schema to contain or reference a homogeneous collection of GML objects shall be derived from `gml:ArrayAssociationType`.

### 23.2.6 Elements Representing Properties

Elements representing properties of GML objects may be declared as global elements in an application schema, or they may be declared locally within object content models (type definitions). Note that elements in the content of complex types that are defined with local names in an application schema will prevent derivation by restriction in another namespace. Such complex types are appropriate for elements intended for use “as is” in their own namespace, and should be declared to be `final="restriction"`. Elements in the content of complex types defined by reference to global elements support derivation by restriction in another namespace, allowing restriction of cardinality, and/or replacement by a member of a substitution group. Such complex types designed for derivation by restriction are appropriate “library types” for elements in substitution groups that cross namespaces.

If the value of the property is expected to be available elsewhere, it is necessary for the property element in an instance to provide a pointer to the value, so the property shall support association by-reference. This is accomplished using `xlink` attributes, and in the GML application schema the XML type for the property shall include `gml:AssociationAttributeGroup`.

If the value of the property is expected to be represented in place, the content model (XML schema type) for the property shall support this. The property element shall either have XML Schema `simpleContent` of the appropriate `simpleType`, or it shall have `complexContent` comprising a **single** child element of the appropriate type.

If the value of the property is expected to be available either elsewhere, or represented in place, then the type for the property element shall support both methods. The type for the property element shall have `gml:AssociationAttributeGroup`, in which all members are optional, and the child element shall have `minOccurs="0"` so that in an instance document the property element may be empty if it carries an `xlink`. Note that the value of a property of an `ArrayAssociationType` shall be represented in place.

If the last pattern is used, and it is desired to prohibit the possibility of both `xlink` attributes and content, or neither, then this constraint should be recorded as a normative directive in an `<annotation>` element on the element declaration in the application schema. The directive may be expressed as prose, or it may be expressed using a formal notation such as Schematron.

## 23.3 Schemas defining Features and Feature Collections

Features and Feature collections are the primary view of geospatial information supported by GML, and are particularly useful in modeling real world geography or in defining message types for geographic web services. A Feature in GML models a real world object or concept and provides an element (feature type) and an associated set of properties describing that type also encoded as elements.

Feature application schemas define geographic features and feature collections for a specific application domain or community . These application schemas shall obey the additional rules described in the following clauses.

### 23.3.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (features, feature collections) of the vocabulary “live”.

### 23.3.2 Import feature.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation=".. / feature.xsd"/>
```

### 23.3.3 Feature Type Derivation

All feature types declared in an application schema shall derive either directly or indirectly from gml:AbstractFeatureType.

The abstract type gml:AbstractFeatureCollectionType may be used as the base type for feature collection types. Alternatively, feature collection types may be specified following the pattern used in this abstract type (directly or indirectly derive from gml:AbstractFeatureType and contain a feature-valued property).

### 23.3.4 Elements Representing Features

All geographic features and feature collections in the application schema shall be declared as global elements in the schema, i.e. they shall be immediate child elements of the XML Schema <schema> element.

The name of an element that instantiates a GML feature shall be its Feature Type, in the sense described in ISO 19109 and 19110.

### 23.3.5 Application Features are Features

A feature defined in an application schema shall conform to the rules respecting GML features as described in Clause 8. These include in particular:

- The name of feature element is the semantic type of the feature.
- The children of a feature are always properties that describe the feature, and such properties can only be encoded as child elements. Properties cannot be encoded as XML attributes.

### 23.3.6 GML Feature Collection Document

A GML application may use a gml:FeatureCollection to contain features defined in an application schema when there is no requirement to restrict the inclusion of other types of features. A GML Application Schema may define specialised feature collection types and global elements to serve as the root elements for documents describing Feature Collections specific to the application domain where there is a requirement to exclude features not defined in that domain.

## 23.4 Schemas defining Geometries

### 23.4.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (geometries) of the vocabulary “live”.

### 23.4.2 Import a GML geometry schema

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../geometryComplexes.xsd"/>
```

### 23.4.3 User-defined Geometry Types and Geometry Property Types

#### 23.4.3.1 User-defined Geometry Types

Authors of application schemas may create their own geometry types if GML lacks the desired construct. To do this, authors shall ensure that these concrete geometry and geometry collection types are subtyped (either directly or indirectly) from the corresponding GML type: `AbstractGeometryType`.

**EXAMPLE** The following complex type definition in an application schema extends the `PointType` of GML and adds a bearing (e.g. for the orientation of a symbol in portrayal).

```
<complexType name="PointWithBearingType">
  <complexContent>
    <extension base="gml:PointType">
      <sequence>
        <element name="bearing" type="gml:AngleType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

Any user-defined geometry subtypes shall inherit the elements and attributes of the base GML geometry types without restriction, but may extend these base types to meet application requirements, such as providing a finer degree of interoperability with legacy systems and data sets.

#### 23.4.3.2 User-defined Geometry Property Types

Furthermore, authors of application schemas may create their own geometry property types that encapsulate geometry types they have defined according to clause 9.1. They shall ensure that these properties follow the pattern used by `gml:GeometryPropertyType`. For standard properties and `gml:GeometryArrayPropertyType` for array properties. The target type shall be a bonafide geometry construct.

A geometry property type may be a restriction of `GeometryPropertyType`, but this is not a requirement. Nevertheless, every geometry property shall follow the pattern of this type. It is allowed to support the choice between a by-value or a by-reference semantic or to restrict the use to either by-value (prohibit the use of the `Xlink` attributes) or by-reference (prohibit the containment of the geometry in the feature).

A geometry array property type may be a restriction of `GeometryArrayPropertyType`, but this is not a requirement. Nevertheless, every geometry property shall follow the pattern of this type. All geometry elements in the array are contained in the feature, only by-value semantics is supported by array properties.

**EXAMPLE** The following complex type definitions in an application schema define a "standard" property type for an user-defined geometry type and an array property type for the same geometry type.

```
<complexType name="MyGeometryPropertyType">
  <sequence>
    <element ref="foo:PointWithBearingType" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup" />
</complexType>

<complexType name="MyGeometryArrayPropertyType">
  <sequence>
    <element ref="foo:PointWithBearingType" minOccurs="0" maxOccurs="unbounded" />
  </sequence>
</complexType>
```

## 23.5 Schemas defining Topologies

### 23.5.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (topologies) of the vocabulary “live”.

### 23.5.2 Import topology.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../topology.xsd"/>
```

### 23.5.3 User-defined Topology Types and Topology Property Types

#### 23.5.3.1 User-defined Topology Types

Authors of application schemas may create their own topology types if GML lacks the desired construct. To do this, authors shall ensure that these concrete topology types are subtyped (either directly or indirectly) from the corresponding GML type: AbstractTopologyType.

Any user-defined topology subtypes shall inherit the elements and attributes of the base GML topology types without restriction, but may extend these base types to meet application requirements, such as providing a finer degree of interoperability with legacy systems and data sets.

#### 23.5.3.2 User-defined Topology Property Types

Furthermore, authors of application schemas may create their own (directed) topology property types that encapsulate topology types they have defined according to section 13. They shall ensure that these properties follow the pattern used by the gml property type for the base gml Topology type, e.g. gml:DirectedNodePropertyType, or gml:TopoVolumePropertyType, or gml:TopoComplexMemberType. The target type shall be a bonafide topology construct.

A topology property type may be a restriction of a Topology PropertyType, but this is not a requirement. Nevertheless, every topology property shall follow the pattern of this type.

## 23.6 Schemas defining Time

### 23.6.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms of the vocabulary “live”.

### 23.6.2 Import temporal.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../temporal.xsd"/>
```

### 23.6.3 User-defined Temporal Types and Temporal Property Types

#### 23.6.3.1 User-defined Temporal Types

Authors of application schemas may create their own temporal types if GML lacks the desired construct. To do this, authors shall ensure that these concrete temporal types are subtyped (either directly or indirectly) from the corresponding GML type: `AbstractTimeObjectType`.

Any user-defined temporal subtypes shall inherit the elements and attributes of the base GML temporal types without restriction, but may extend these base types to meet application requirements, such as providing a finer degree of interoperability with legacy systems and data sets.

#### 23.6.3.2 User-defined Temporal Property Types

Furthermore, authors of application schemas may create their own temporal property types that encapsulate temporal types they have defined according to section 13. They shall ensure that these properties follow the pattern used by the gml property type for the base GML temporal type, e.g. `gml:TimeInstantPropertyType`. The target type shall be a bonafide temporal construct.

A temporal property type may be a restriction of a `Temporal PropertyType`, but this is not a requirement. Nevertheless, every temporal property shall follow the pattern of this type.

## 23.7 Schemas defining Coordinate Reference Systems

Many of the concrete XML elements defined in the CRS Schemas can be used without Application Schemas, whenever no content extensions or restrictions are needed. An Application Schema shall be used whenever element contents extension is required, and should be used in most other cases to specify needed restrictions. That is, an Application Schema should be defined to extend and/or restrict elements as needed for a specific application, or a set of applications, to:

- a) Add elements to contents of existing elements, for recording additional data about that item needed for that application.
- b) Restrict the multiplicity of current contents elements, to eliminate flexibility not needed and perhaps confusing for that application.
- c) Use a different element name, to be more easily understood in that specific application, primarily for elements that will be instantiated many times.
- d) Specify standard contents and contents patterns for selected elements and attributes, as needed to improve interoperability.
- e) Specify standard XML and other documents to be referenced or otherwise used, as needed to improve interoperability.

Application Schemas can thus be used for XML document contents extensions, restrictions, or both. Contents extension is expected to be often used to record additional data needed for applications. Contents restriction is expected to be frequently used to restrict contents, in order to increase interoperability and reduce ambiguity when greater flexibility is not needed for applications. Extensions of existing concrete elements can be defined by extending that concrete element. In many cases, restrictions of existing concrete elements can be done by extending the abstract element from which that concrete element is derived, by adding somewhat different but corresponding extensions.

An Application Schema can specify a single top level element for use in an XML document, with the XML elements and types that it uses. That single top level XML element can be an object with identity, but this is not required. Such an Application Schema will import and build upon one or more of the six XML Schemas specified in this document.

Application Schemas could define additional concrete elements using or extending other abstract elements, if needed. However, an additional concrete element using or extending an abstract element should not be defined if that concrete element is largely similar to an existing element, and thus probably should extend or use an existing concrete element. In many cases, the existing concrete elements that use an abstract element are believed to be largely exhaustive. This is particularly true when the existing concrete elements include one element that is quite general, such as the elements EngineeringCRS, DerivedCRS, EngineeringDatum, UserDefinedCS, OperationParameter, and OperationParameterGroup.

The Conversion, Transformation, ParameterValue, and ParameterValueGroup elements can be used for well-known coordinate operation methods, especially when only one instance of that element is needed for that operation method. However, these elements should not be used for well-known coordinate operation methods when many instances of that element are needed for one operation method. Instead, an Application Schema that defines operation-method-specialized element names and contents should be prepared for each such operation method. Subclauses F.3 and F.4 provide examples of such Application Schemas. For interoperability, a suitable geospatial information community should standardize each such Application Schema.

NOTE This use of Application Schemas follows the patterns used in Feature Application Schemas.

### 23.7.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (coordinate reference systems) of the vocabulary “live”.

### 23.7.2 Import coordinateReferenceSystem.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../coordinateReferenceSystem.xsd"/>
```

## 23.8 Schemas defining Coverages

Coverages are an alternative view of geospatial information. This view focuses on the variation of a property or properties across a domain, so is particularly useful in analysis.

This clause defines the rules for the construction of application schemas for coverages. Note that coverages are features and hence the rules of section 23.3 above apply also to coverages.

### 23.8.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (coordinate reference systems) of the vocabulary “live”.

### 23.8.2 Import coverage.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../coverage.xsd"/>
```

### 23.8.3 Coverages shall derive from gml:AbstractDiscreteCoverageType or gml:AbstractContinuousCoverageType

All geographic coverages in the application schema shall be declared as global elements in the schema, that is they shall be child elements of the XML Schema <schema> element. The content model for such global elements shall derive by extension either directly or indirectly from gml:AbstractDiscreteCoverageType or

`gml:AbstractContinuousCoverageType`. Note that these types derive indirectly from `gml:AbstractFeatureType` and hence the condition of the feature model is satisfied.

The `coverage.xsd` provides the specific coverage types (`MultiPointCoverage`, `MultiCurveCoverage`, `MultiSurfaceCoverage`, `MultiSurfaceCoverage`, `GriddedCoverage`, `RectifiedGridCoverage`) and application coverages can derive from any of these as well.

#### 23.8.4 Range Parameters shall be Derived from `gml:ValueType`

The coverage application schema shall define or import the definitions for all Range Parameters. Each such Range Parameter shall be substitutable for `gml:_Value` as defined in the `valueObjects.xsd` schema. Note that this allows the Range Parameter to take on a wide range of types. Note further that the `value.xsd` provides several abstractsub- sub-types that are substitutable for `gml:_Value`, including `gml:_ScalarValue` and `gml:_ValueList`. Concrete scalar and value list types, and substitution group head elements, are also provided (substitutable for `gml:_ScalarValue` or `gml:_ValueList`) and include:

- `gml:Category` ( `gml:CodeType` )
- `gml:CategoryList` ( `gml:CodeOrNullListType` )
- `gml:Quantity` ( `gml:MeasureType` )
- `gml:QuantityList` ( `gml:MeasureOrNullListType` )
- `gml:Count` ( `gml:CountType` )
- `gml:Boolean` ( `gml:BooleanType` )

To define the Range Parameters in a Coverage Application schema, refer to the `valueObjects.xsd` schema described in Annex C.

Typical examples of the use of the value types in the development of a GML coverage can be found in the examples clause for coverages Clause 19.3, and are summarized in Table 8.

**Table 8 – Range Parameters for Coverage Schemas**

Coverage	Range Parameter	Definition in GML
Temperature Distribution (weather)	Temperature	Would be derived from <code>gml:MeasureOrNullListType</code> and made substitutable for <code>gml:measure</code> defined in the <code>measures.xsd</code> .
Soil type distribution (agronomy)	Soil type	Would be derived from <code>gml:Category</code> and made substitutable for <code>gml:Category</code> . Weak reference to an enumeration of soil types.
Multi-spectral optical image (remote sensing)	Reflectance in each spectral band.	Would be derived from <code>gml:QuantityListType</code> and made substitutable for <code>gml:QuantityList</code> .
Distribution of West Nile Virus cases. (epidemiology)	CaseCount	Would be derived from <code>integerOrNullList</code> , and made substitutable for <code>gml:CountList</code> .
Distribution of West Nile Virus cases. (epidemiology)	CaseCount	Would be derived from <code>integerOrNullList</code> , and made substitutable for <code>gml:CountList</code> .

### 23.8.5 Coverage Document

A coverage document is defined by a corresponding coverage schema. The root element of this document shall be a coverage defined in this schema or may be a feature collection whose members are coverages as described in Clause 8.2.7.

## 23.9 Schemas defining Observations

An observation in GML is a kind of feature that represents an act of observing or observation event. This may be associated with a measurement obtained from some type of instrument, or may just be a photograph acquired by a travelling tourist.

This clause describes how to create an observation application schema.

An observation application schema defines one or more types of observations according to the following rules.

### 23.9.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (observation) of the vocabulary “live”.

### 23.9.2 Import observation.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../observation.xsd"/>
```

### 23.9.3 Observations shall derive from gml:ObservationType

All observation types (kinds of observations) defined in the application schema shall be declared as global elements in the schema, that is they shall be child elements of the XML Schema <schema> element. The content model for such global elements shall derive by extension either directly or indirectly from gml:ObservationType.

### 23.9.4 Observation Collections shall derive from gml:CollectionType

All observation collections in the application schema shall be declared as global elements in the schema, that is they shall be child elements of the XML Schema <schema> element. The content model for such global elements shall derive by extension either directly or indirectly from gml:CollectionType.

### 23.9.5 Observations are Features

An observation defined in an application schema shall conform to the rules respecting GML features as described in Clause 8. These include in particular:

- a) Observation semantic type information can ONLY be carried by elements. The following is not valid GML.

```
<abc:Measurement type="WaterQuality"> ... </abc:Measurement>
```

- b) The children of a observation are always properties that describe the observation, and such properties can only be encoded as child elements. Properties cannot be encoded as XML attributes.

c) No child of an observation can itself be a feature or other GML object (i.e. one derived from `gml:AbstractGMLType`). Thus no child of a observation can be feature, geometry, topology, coordinate reference system etc.

### 23.9.6 Observation Collection Document

Corresponding to a Observation Collection document there shall be a GML Application Schema that defines the single root element of that Observation Collection document. Note that this does not imply that this Observation Collection is defined by a single application schema. The features referenced from the Observation Collection element may be contained in any number of other schemas and these may define observations only, observation collections or any combination of the same.

An observation collection could be used, for example, to encode a set of measurements from one or more sensor devices.

## 23.10 Schemas defining Dictionaries and Definitions

A common requirement is to collect a set of definitions together into a dictionary, in order that a term may be referred to many times, while its (potentially lengthy) definition is only recorded once. The kind of information that might form the content of a dictionary are units of measure, coordinate reference systems, observable-types or measurands, parties including individuals or organizations.

In order to support this, some generic components for dictionaries and definitions are provided in GML 3. The basic Definition is a simple element which supports a prose description. This may be used directly for simple non-parameterised definitions, or may serve as the basis for specialized definition elements.

The basic Dictionary is a bag of Definitions. It may be used as a container for an arbitrary set of Definitions or elements that are in the Definition substitution group. It may also serve as the basis for a specialized Dictionary restricted to contain only certain types of definition.

One set of specialized definitions is built in to GML 3, for units of measure, and serves as an example of how to derive specialized definition components.

This clause describes how to create an application schema for definitions.

An application schema for definitions defines one or more types of definitions according to the following rules.

### 23.10.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (dictionaries, definitions) of the vocabulary “live”.

### 23.10.2 Import dictionary.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../dictionary.xsd"/>
```

### 23.10.3 Definitions shall derive from `gml:DefinitionType`

All definitions in the application schema shall be declared as global elements in the schema, i.e. they shall be immediate child elements of the XML Schema `<schema>` element. The content model for such global elements shall derive either directly or indirectly from `gml:DefinitionType`.

#### 23.10.4 Dictionaries shall derive from gml:DictionaryType

A dictionary in the application schema shall be declared as a global element in the schema, that is it shall be a child element of the XML Schema <schema> element. The content model for such global elements shall derive either directly or indirectly from gml:DictionaryType.

#### 23.11 Schemas defining Values

GML allows for user defined value types. Such values types can be used to express the property types of features and other types of GML objects. The basic root types for user-defined values are defined in basicTypes.xsd. An alternative form for the expression of values is contained in valueObjects.xsd. This is used mainly to provide values for the gml:resultOf parameter for an observation.

##### 23.11.1 Target Namespace

The application schema shall declare a target namespace as described in section 22.3.1 Target Namespace, in which the terms (values) of the vocabulary “live”.

##### 23.11.2 Import valueObjects.xsd or basicTypes.xsd

The application schema shall import the necessary components from GML 3 as described in section 22.3.2 Import GML Schema, for example as follows:

```
<import namespace="http://www.opengis.net/gml" schemaLocation="../valueObjects.xsd"/>
```

##### 23.11.3 Construction of New Value Types

New value types can be created by derivation (typically by restriction) from any of the root types shown in Table 9.

**Table 9**

Content Model	Description
MeasureType	A numerical quantity with a unit of measure (UOM)
CategoryType	A classification
CountType	A count of occurrences, incidences etc.

Some standard value types can be found in the measures.xsd schema.

## Annex A (normative)

### Abstract Test Suite

#### **A.1 Conformance Class A. Conformance of the XML Implementation of GML data**

##### **A.1.1 Existence of an applicable GML application schema.**

- a) Test Purpose: To verify the existence of a GML application schema applicable to the GML data set.
- b) Test Method: Ensure that the application schema applicable to a particular GML data set exists.
- c) Reference:
- d) Test Type: Basic Test

##### **A.1.2 Conformance of the applicable application schema**

- a) Test Purpose: To verify that the applicable GML application schema is conformant to this specification.
- b) Test Method: Test whether the application schema satisfies all the tests specified in the Conformance Class B.
- c) Reference:
- d) Test Type: Capability Test.

##### **A.1.3 Conformance of the data set**

- a) Test Purpose: To verify the validity of the GML data against the conformant GML application schema.
- b) Test Method: Validate GML Data set against corresponding GML application schema tested in the steps A1.1-A1.2. The process may be using an appropriate software tool for validation or be a manual process that checks all relevant definitions from the GML and application schemas.
- c) Reference:
- d) Test Type: Capability Test

#### **A.2 Conformance Class B. Conformance of the XML Implementation of GML Application Schema**

##### **A.2.1 XMLSchema valid**

- a) Test Purpose: To verify the conformance of the GML application schema to the XML and XMLSchema specifications.

- b) Test Method: Validate GML application schema using appropriate process for validation. The process may be using an appropriate software tool for validation or be a manual process that checks all relevant rules from the XML 1.0 and XMLSchema 1.0 specifications.
- c) Reference:
- d) Test Type: Capability Test

### **A.2.2 GML model valid**

- a) Test Purpose: To verify the validity against GML model.
- b) Test Method: Ensure that the schema conforms to Clause 23 of this specification (Rules for creating GML Application Schemas) and 22(Profiles).
- c) Reference:
- d) Test Type: Basic Test

## **A.3 Conformance Class C. Conformance of the GML Interface Implementation for GML Data**

### **A.3.1 Serialization capability test**

- a) Test Purpose: To verify the existence of the serialization operation of the implementation.
- b) Test Method: Verify that the implementation implements the serialize operation that produces GML in XML format.
- c) Reference:
- d) Test Type: Basic Test

### **A.3.2 Serialization validity test**

- a) Test Purpose: To verify that the result of the implementation serialization is conformant with this specification.
- b) Test Method: Verify that the result of the serialization of the implementation conforms to this specification according to the Conformance Class A (A.1)
- c) Reference:
- d) Test Type: Capability Test

### **A.3.3 Transforming to and from XML format**

- a) Test Purpose: To verify that the creation of implementation's objects from GML source in XML format, if that capability exists, performs valid function.
- b) Test Method: If it is possible to create implementation's objects from GML source in XML format, verify that successive actions of object creation and serialization produce (test A.3.2) the result that is identical to the source (no loss of information).
- c) Reference:

- d) Test Type: Capability Test

## **A.4 Conformance Class D. Conformance of the GML Interface Implementation for GML Application Schema**

### **A.4.1 Serialization capability test**

- a) Test Purpose: To verify the existence of the serialization operation of the implementation.
- b) Test Method: Verify that the implementation implements the serialize operation that produces GML Application Schema in XML Schema format.
- c) Reference:
- d) Test Type: Basic Test

### **A.4.2 Serialization validity test**

- a) Test Purpose: To verify that the result of the implementation serialization is conformant with this specification.
- b) Test Method: Verify that the result of the serialization of the implementation conforms to this specification according to the Conformance Class B (A.2)
- c) Reference:
- d) Test Type: Capability Test

### **A.4.3 Transforming to and from XML format**

- a) Test Purpose: To verify that the creation of implementation schema objects from GML Application Schema source in XML format, if that capability exists, performs valid function.
- b) Test Method: If it is possible to create implementation's schema objects from GML Application Schema source in XML format, verify that successful actions of object creation and serialization produce (test A.4.2) the result that is identical to the source (without loss of information).
- c) Reference:
- d) Test Type: Capability Test

## Annex B (normative)

### Conformance

#### B.1 GML Object Rules

This clause summarizes the rules for the detection of GML objects. These rules specify the necessary and sufficient conditions for an element.

##### B.1.1 GML Objects

An element *x* is a GML object (of some kind) iff its content model derives ultimately from `gml:AbstractGMLType`, so that it may have identity provided by a `gml:id` attribute.

An element *x* is a more specific kind of GML object iff its content model derives ultimately from a more specific GML complex type derived from `AbstractGMLType`. For example, an element *x* is a GML feature iff its content model derives ultimately from `gml:AbstractFeatureType`. An element *x* is a GML geometry iff its content model derives ultimately from `gml:AbstractGeometryType`. And so on.

##### B.1.2 GML Properties

An element *p* is a property of a GML object *x* iff *p* is a child of *x* in the XML sense.

#### B.2 Application Schemas

Writers of application schemas shall conform to the rules stated in clauses 7 - 23.

#### B.3 Conformance Classes

##### B.3.1 Conformance Requirements

Conformance with this specification shall be checked using all the relevant tests specified in Annex A. The framework, concepts, and methodology for testing, and the criteria to be achieved to claim conformance, are specified in ISO 19105: Geographic information — Conformance and Testing.

This OpenGIS<sup>®</sup> specification defines four conformance classes: A, B, C and D. Any product claiming conformance with one of these classes shall pass all the requirements described in the corresponding abstract test suite specified in the Annex A.

- 1. Class A: Conformance of the XML Implementation of GML Data Set.**  
This class applies to GML data encoded using XML.
- 2. Class B: Conformance of the XML Implementation of GML Application Schemas.**  
This class applies to GML application schemas encoded using XML Schema schema description language.

3. **Class C: Conformance of Interface Implementations for GML Data.**  
This class applies to implementations of software interfaces that consume and/or produce GML data.
4. **Class D: Conformance of Interface Implementations for GML Application Schemas.**  
This class applies to implementations of software interfaces that consume and/or produce GML application schemas.

# Annex C (normative)

## GML Schemas

### C.1 basicTypes.xsd

```
<?xml version="1.0" encoding="UTF-8"?>
<schema targetNamespace="http://www.opengis.net/gml" xmlns:gml="http://www.opengis.net/gml"
xmlns:xlink="http://www.w3.org/1999/xlink" xmlns:sch="http://www.ascc.net/xml/schematron"

  <annotation>
    <documentation>A coordinate reference system consists of an ordered sequence of coordinate system axes that are
related to the earth through a datum. A coordinate reference system is defined by one datum and by one coordinate system. Most
coordinate reference system do not move relative to the earth, except for engineering coordinate reference systems defined on
moving platforms such as cars, ships, aircraft, and spacecraft. For further information, see OGC Abstract Specification Topic 2.
Coordinate reference systems are commonly divided into sub-types. The common classification criterion for sub-typing of
coordinate reference systems is the way in which they deal with earth curvature. This has a direct effect on the portion of the
earth's surface that can be covered by that type of CRS with an acceptable degree of error. The exception to the rule is the
subtype "Temporal" which has been added by analogy. </documentation>

<!-- ===== -->
<element name="anchorPoint" type="gml:CodeType">
  <annotation>
    <documentation>Description, possibly including coordinates, of the point or points used to anchor the datum to the
Earth. Also known as the "origin", especially for engineering and image datums. The codeSpace attribute can be used to
reference a source of more detailed on this point or surface, or on a set of such descriptions.
- For a geodetic datum, this point is also known as the fundamental point, which is traditionally the point where the relationship
between geoid and ellipsoid is defined. In some cases, the "fundamental point" may consist of a number of points. In those cases,
the parameters defining the geoid/ellipsoid relationship have been averaged for these points, and the averages adopted as the
datum definition.
- For an engineering datum, the anchor point may be a physical point, or it may be a point with defined coordinates in another
CRS. When appropriate, the coordinates of this anchor point can be referenced in another document, such as referencing a GML
feature that references or includes a point position.
- For an image datum, the anchor point is usually either the centre of the image or the corner of the image.
- For a temporal datum, this attribute is not defined. Instead of the anchor point, a temporal datum carries a separate time origin
of type DateTime. </documentation>
  </annotation>
</element>
<!-- ===== -->
<element name="realizationEpoch" type="date">
  <annotation>
    <documentation>The time after which this datum definition is valid. This time may be precise (e.g. 1997.0 for IRTF97)
or merely a year (e.g. 1983 for NAD83). In the latter case, the epoch usually refers to the year in which a major recalculation of
the geodetic control network, underlying the datum, was executed or initiated. An old datum can remain valid after a new datum is
defined. Alternatively, a datum may be superseded by a later datum, in which case the realization epoch for the new datum
defines the upper limit for the validity of the superseded datum. </documentation>

string segments cannot support continuity above C 0 , since there is no spare control parameter to adjust the incoming angle at
the end points of the segment. Spline functions on the other hand often have extra degrees of freedom on end segments that
allow them to adjust the values of the derivatives to support C 1 or higher continuity.</documentation>

```

direction of the offset curve from the basis curve. It can be omitted in the 2D case, where the distance can be positive or negative. In that case, distance defines left side (positive distance) or right side (negative distance) with respect to the tangent to the basis curve.

In 3D the basis curve shall have a well defined tangent direction for every point. The offset curve at any point in 3D, the basis curve shall have a well-defined tangent direction for every point. The offset curve at any point (parameter) on the basis curve c is in the direction

$$s = v \times t \text{ where } v = c.refDirection() \text{ and } t = c.tangent()$$

For the offset direction to be well-defined, v shall not on any point of the curve be in the same, or opposite, direction as

t.

The default value of the refDirection shall be the local co-ordinate axis vector for elevation, which indicates up for the curve in a geographic sense.

NOTE! If the refDirection is the positive tangent to the local elevation axis ("points upward"), then the offset vector points to the left of the curve when viewed from above.

<!-- ===== -->
<element name="AffinePlacement" type="gml:AffinePlacementType"/>
<!-- ===== -->
<complexType name="AffinePlacementType">
```

<documentation> A placement takes a standard geometric construction and places it in geographic space. It defines a transformation from a constructive parameter space to the co-ordinate space of the co-ordinate reference system being used. Parameter spaces in formulae in this International Standard are given as (u, v) in 2D and (u, v, w) in 3D. Co-ordinate reference systems positions are given in formulae, in this International Standard, by either (x, y) in 2D, or (x, y, z) in 3D.

Affine placements are defined by linear transformations from parameter space to the target co-ordinate space. 2-dimensional Cartesian parameter space, (u,v) transforms into 3-dimensional co-ordinate reference systems, (x,y,z) by using an affine transformation, (u,v) -> (x,y,z) which is defined :

$$\begin{matrix} x & u_x & v_x & x_0 \\ & u & & \\ y & u_y & v_y & + y_0 \\ & v & & \\ x & u_x & v_x & z_0 \end{matrix}$$

Then, given this equation, the location element of the AffinePlacement is the direct position (x0, y0, z0), which is the target position of the origin in (u, v). The two reference directions (ux, uy, uz) and (vx, vy, vz) are the target directions of the unit vectors at the origin in (u, v).

<complexType name="AbstractGriddedSurfaceType">
  <annotation>
    <documentation> A gridded surface is a parametric curve
surface derived from a rectangular grid in the parameter
space. The rows from this grid are control points for
horizontal surface curves; the columns are control points
for vertical surface curves. The working assumption is that
for a pair of parametric co-ordinates (s, t) that the
horizontal curves for each integer offset are calculated
and evaluated at "s". The defines a sequence of control
points:
  </documentation>
  </annotation>

```

cn(s) : s 1 .....columns

From this sequence a vertical curve is calculated for "s", and evaluated at "t". In most cases, the order of calculation (horizontal-vertical vs. vertical-horizontal) does not make a difference. Where it does, the horizontal-vertical order shall be the one used.

Logically, any pair of curve interpolation types can lead to a subtype of GriddedSurface. The following clauses define some most commonly encountered surfaces that can be represented in this manner.

```

<!-- ===== -->
<element name="Sphere" type="gml:SphereType" substitutionGroup="gml:_GriddedSurface"/>
<!-- ===== -->
<complexType name="SphereType">
  <annotation>
    <documentation> A sphere is a gridded surface given as a
family of circles whose positions vary linearly along the
axis of the sphere, and whose radius varies in proportions to
the cosine function of the central angle. The horizontal
circles resemble lines of constant latitude, and the vertical
arcs resemble lines of constant longitude.
NOTE! If the control points are sorted in terms of increasing
longitude, and increasing latitude, the upNormal of a sphere
is the outward normal.
EXAMPLE If we take a gridded set of latitudes and longitudes
in degrees,(u,v) such as

(-90,-180) (-90,-90) (-90,0) (-90, 90) (-90, 180)
(-45,-180) (-45,-90) (-45,0) (-45, 90) (-45, 180)
( 0,-180) ( 0,-90) ( 0,0) ( 0, 90) ( 0, 180)
( 45,-180) ( 45,-90) ( 45,0) ( 45, -90) ( 45, 180)
( 90,-180) ( 90,-90) ( 90,0) ( 90, -90) ( 90, 180)

And map these points to 3D using the usual equations (where R
is the radius of the required sphere).

z = R sin u
x = (R cos u)(sin v)
y = (R cos u)(cos v)

We have a sphere of Radius R, centred at (0,0), as a gridded
surface. Notice that the entire first row and the entire last
row of the control points map to a single point in each 3D
Euclidean space, North and South poles respectively, and that
each horizontal curve closes back on itself forming a
geometric cycle. This gives us a metrically bounded (of finite
size), topologically unbounded (not having a boundary, a
cycle) surface.

any GML types - Geometries, Topologies, Features ...

```

"FeatureCollections" may only contain Features. "GeometryCollections" may only contain Geometry's. "Bags" are less constrained – they must contain objects that are substitutable for gml:\_Object. This may mix several levels, including Features, Definitions, Dictionaries, Geometries etc.

The content model would ideally be

```

member 0..*
members 0..1
member 0..*

```

for maximum flexibility in building a collection from both homogeneous and distinct components:  
included "member" elements each contain a single Object  
an included "members" element contains a set of Objects

However, this is non-deterministic, thus prohibited by XSD.

  <!-- ===== -->
  <complexType name="AssociationType">
    <annotation>

```

<documentation> A pattern or base for derived types used to specify complex types corresponding to an unspecified UML association - either composition or aggregation. Restricts the cardinality of Objects contained in the association to a maximum of one. An instance of this type can contain an element representing an Object, or serve as a pointer to a remote Object.

Descendents of this type can be restricted in an application schema to

- \* allow only specified classes as valid participants in the aggregation
- \* allow only association by reference (i.e. empty the content model) or by value (i.e. remove the xlink).

When used for association by reference, the value of the gml:remoteSchema attribute can be used to locate a schema fragment that constrains the target instance.

In many cases it is desirable to impose the constraint prohibiting the occurrence of both reference and value in the same instance, as that would be ambiguous. This is accomplished by adding a directive in the annotation element of the element declaration. This directive can be in the form of normative prose, or can use a Schematron pattern to automatically constrain co-occurrence - see the declaration for \_strictAssociation below.

If co-occurrence is not prohibited, then both a link and content may be present. If this occurs in an instance, then the rule for interpretation is that the instance found by traversing the href provides the normative value of the property, and should be used when possible. The value(s) included as content may be used if the remote instance cannot be resolved. This may be considered to be a "cached" version of the value(s). <documentation>

  elements and types
  <!-- ===== -->
  <!-- This schema uses the gml:MeasureType defined in basicTypes.xsd with the modified meaning:

```

<documentation>Value of a quantity, with its units. This element uses the XML Schema primitive data type "double" because it supports both decimal and scientific notation, and thus offers flexibility and precision. However, there is no requirement to store values using any particular format, and applications receiving elements of this type may choose to coerce the data to any other type as convenient. The XML attribute uom references the units or scale by which the amount should be multiplied. For a reference within the same XML document, the abbreviated XPointer prefix "#" symbol should be used, followed by a text abbreviation of the unit name. However, the "#" symbol may be optional, and still may be interpreted as a reference.  
</documentation> -->

## C.23 referenceSystems.xsd

```

<?xml version="1.0" encoding="UTF-8"?>
<schema targetNamespace="http://www.opengis.net/gml" xmlns:gml="http://www.opengis.net/gml"
xmlns="http://www.w3.org/2001/XMLSchema" elementFormDefault="qualified" version="3.1.0" xml:lang="en">
  <annotation>
    <appinfo source="urn:opengis:specification:gml:schema-referenceSystems"/>
    <documentation>
      <name>referenceSystems.xsd</name>
      <version>3.1.0</version>
      <scope>How to encode reference system definitions. </scope>
      <description>Builds on several other parts of GML 3 to encode the data needed to define reference systems. Primary
editor: Arliss Whiteside. Last updated 2003/10/16. </description>
      <copyright>Copyright (c) 2002-2003 Open GIS Consortium, All Rights Reserved.</copyright>
      <conformance>This schema encodes the Reference System (RS_) package of the extended UML Model for OGC
Abstract Specification Topic 2: Spatial Referencing by Coordinates. That UML model is adapted from ISO 19111 - Spatial
referencing by coordinates, as described in Annex C of Topic 2. The SC_CRS class is also encoded here, to eliminate the
(circular) references from coordinateOperations.xsd to coordinateReferenceSystems.xsd. The
RS_SpatialReferenceSystemUsingGeographicIdentifier class is not encoded, since it is not applicable to coordinate positions.
The CI_Citation class is not directly encoded, since such information can be included as metaDataProperty elements which are
optionally allowed. A modified version of the EX_Extent (DataType) class from ISO 19115 is currently encoded here, using GML
3 schema types. (A more extensive version of the EX_Extent package might be XML encoded in the future, probably in a
separate extent.xsd schema.) </conformance>

    <documentation xml:lang="en">
      The temporal topology schema for ISO19136 provides constructs for handling topological complexes and
      temporal feature relationships.
      Temporal geometric characteristics of features are represented as instants and periods.
      While, temporal context of features that does not relate to the position of time is described as connectivity relationships
      among instants and periods. These relationships are called temporal topology as they do not change in time,
      as long as the direction of time does not change.
      It is used effectively in the case of describing a family tree expressing evolution of species, an ecological cycle,
      a lineage of lands or buildings, or a history of separation and merger of administrative boundaries.
      This schema reflects a partial yet consistent implementation of the model described in ISO 19108:2002.

## Annex D (informative)

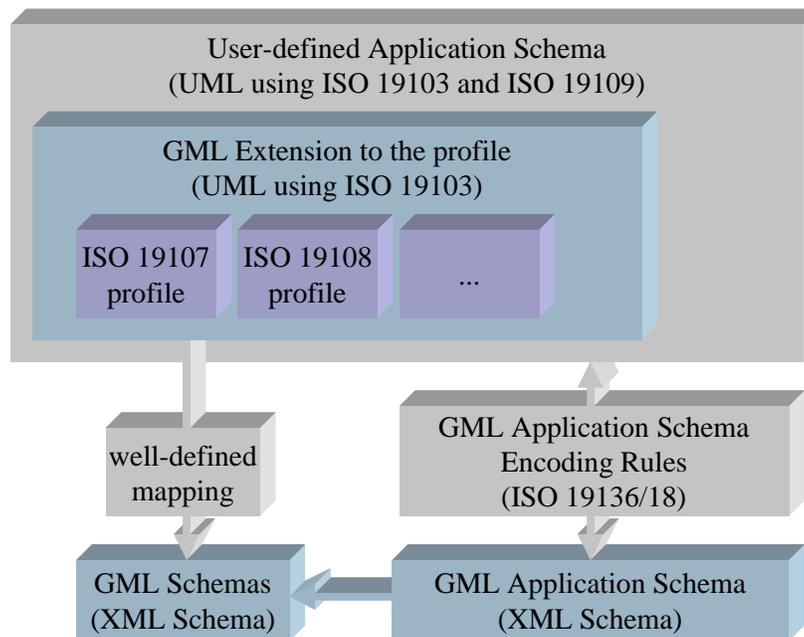

### ISO 19100 Profile and Application Schema of GML

#### D.1 General Approach

The approach taken by this standard is shown in the following diagram. The two main aspects are:

- Clear documentation of the conceptual model of GML: The profile of the ISO 19100 harmonized model that is implemented by GML is documented as well as the extensions to this profile.
- Support for application schema development either in UML or XML Schema: In order to achieve this two-way mapping between UML (i.e. ISO 19109 Application Schemas in UML) and XML Schema (i.e. GML Application Schemas in XML Schema) the constructs used in both representations have to be limited. While this reduces the expressiveness of the schema descriptions to some extent, this also reduces their complexity and may make it easier to implement them.

**NOTE** While the mapping from UML to XML Schema is discussed in Annex A of ISO DIS 19118, the reverse mapping is not discussed in any other ISO 19100 standard.

**Figure 12**

#### D.2 Profile of the ISO 19100 Harmonized Model used by GML

This section describes the profile of the ISO 19100 Harmonized Model that is used by GML. The description is based on version 4.5 of the model. In the description of the class diagrams of the profile the relationship and mapping to the GML Schemas is discussed.

NOTE Two types of differences between the ISO 19100 harmonized model and GML have been identified in this process:

- Differences in concepts. These shall be discussed, whether the difference is acceptable, GML is more appropriate or ISO 19100 is more appropriate.
- In general the encoding rules discussed in Annex E are used also in the encoding of the GML Schemas. However, since the GML Schemas were mostly handcrafted they exploit more of the specific capabilities of the implementation environment, i.e. XML and XML Schema. Examples are a number of predefined basic types (simple or complex types with simple content) or the use of global elements also for properties that shall be made substitutable (e.g. to define aliases for deprecated property names). These cases are documented in the following clauses or are straightforward.

Only elements from packages discussed below are part of the profile. All other elements are not part of the profile<sup>2</sup>.

Due to the nature of GML no operation of any class is part of the profile.

In addition, interface classes (stereotype <<Interface>>) without data structures and “Realization” relationships to classes without data structures have been deleted.

Furthermore, the navigability of associations has been restricted to the directions in which GML represents explicit object properties (most associations in the GML Schemas are navigable only in a single direction).

NOTE 1 All deprecated types, elements and attributes of GML are not considered in this annex.

NOTE 2 The general rules for the UML-to-XML-Schema mapping for GML Application Schemas is defined in Annex E.

NOTE 3 In this annex the namespace "xsd:" is used to refer to the namespace of XML Schema, which is "http://www.w3.org/2001/XMLSchema". The namespace "gml:" refers to the namespace of GML, which is "http://www.opengis.net/gml".

## D.2.1 ISO 19103 Conceptual Schema Language

In this section we define the basic types defined in ISO PDTS 19103 that are directly available in GML. In many cases simple types defined by XML Schema are used directly.

- “CharacterString” is implemented by xsd:string. The character encoding is defined in the processing instruction of the XML document (the default for XML documents is UTF-8).
- „Date” is implemented by xsd:date. DatePrecision is not supported.
- “DateTime” is implemented by xsd:dateTime. Again, DatePrecision is not supported.
- “Time” is implemented by xsd:time.
- “Real” is implemented by xsd:double.
- “Decimal” is in general implemented by xsd:decimal. For practical reasons, often decimal values will also be represented in schemas by xsd:double.
- The generic basic type “Number” is in general implemented in GML Schemas by xsd:double.
- “Integer” is implemented by xsd:integer.

---

<sup>2</sup> The deleted packages are: ISO 19110, ISO 19112, ISO 19116, ISO 19117, ISO 19118, ISO 19119, ISO 19128, ISO 19133, ISO 19134, ISO GDF, ISO 00639 Human Language, all informative packages, New.

- “Boolean” is implemented by xsd:boolean.
  - “Measure” is implemented by the simple type gml:MeasureType. The value is of type xsd:double, the uom-specifier is implemented by a URI to a <gml:UnitDefinition> element. The following subtypes are implemented by GML, each pointing to a corresponding unit definition (measure.xsd):
    - “Length” → gml:LengthType
    - “Scale” → gml:ScaleType
    - “Area” → gml:AreaType
    - “Volume” → gml:VolumeType
    - “Velocity” → gml:SpeedType
- NOTE This terminology is incorrect in ISO 19103: velocity is a vector quantity, so may only be described by a single component when operating within a 1-D coordinate system.
- “Time” → gml:TimeType
  - “Angle” → gml:AngleType
  - “Vector” is implemented by gml:VectorType.
  - “GenericName“, „LocalName“ and „ScopedName“ are implemented by gml:CodeType where the name space designator is a URI.
  - “Measure” is implemented by gml:MeasureType, the uom-attribute is a URI pointing to the unit definition.
  - “UnitOfMeasure” is implemented by gml:UnitDefinitionType.

ISO PDTS 19103 specifies that all NULL values are equivalent. GML uses a more explicit approach by requiring additional information about the reason for the NULL value. Whether an application uses this added information or not is optional.

## D.2.2 ISO 19107 Spatial Schema (Geometry)

### D.2.2.1 Overview

The UML model of the GML profile defined in this annex describes a conceptual model of the abstract types defined in ISO 19107. The same names for the classes and their properties as in ISO 19107 are used to document the GML profile to ease the comparison with that standard.

NOTE See chapter 2 of ISO 19107 for more details.

The following additional changes have been applied to the geometry package of ISO 19107.

**Table 10**

Change	Explanation
GM_Primitive: association „Interior to“ deleted	Currently not supported by GML
GM_Polygon: attribute „SpanningSurface“ deleted	Currently not supported by GML
GM_Solid: converted the operation “boundary()” to an attribute	As the boundary of GM_Solid is accessible only via the „boundary()“ operation, an attribute of the same name has been added. The attribute value is the result of the “boundary()” operation as defined in ISO 19107.

GM_Complex: association „Contains“ deleted	Currently not supported by GML
Derived attributes deleted in GM_MultiPrimitive subtypes	These attributes can be derived from the digital representation of the objects, therefore the redundant information has been omitted
GM_CompositePoint: deleted	GM_CompositePoint does not add any additional information. The type has been added in ISO 19107 for completeness only, but it is not expected that it will be used in GML documents. Therefore, it has been omitted in GML.
GM_PolynomialSpline has been made abstract	Currently not instantiable in GML, but the subtype GM_CubicSpline is.
GM_LineSegment: deleted	Not supported by GML, a GM_LineString with two control points shall be used instead
GM_CurveBoundary: deleted	Only used in operations
GM_ComplexBoundary: deleted	Only used in operations

NOTE GM\_OrientableCurve and GM\_OrientableSurface have been changed to “not abstract” (in accordance with ISO DIS 19107).

#### D.2.2.2 Geometry root

The following UML class diagrams illustrate the profile of the “Geometry root” package (compare with figures 5 to 6 of ISO 19107).

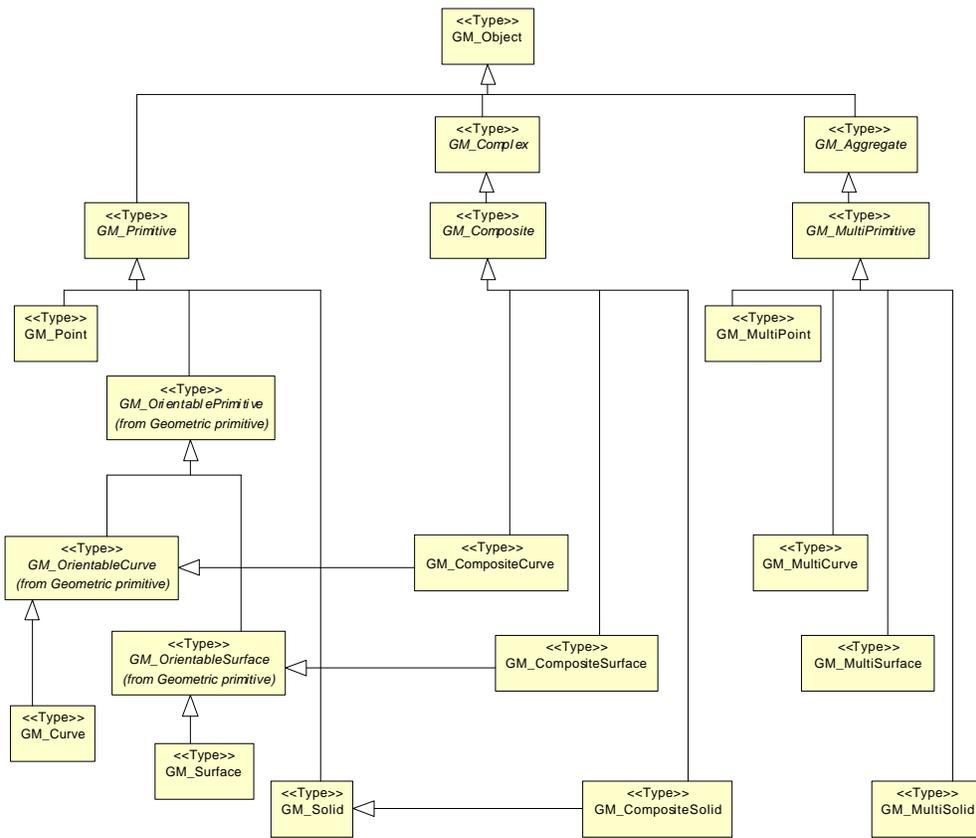

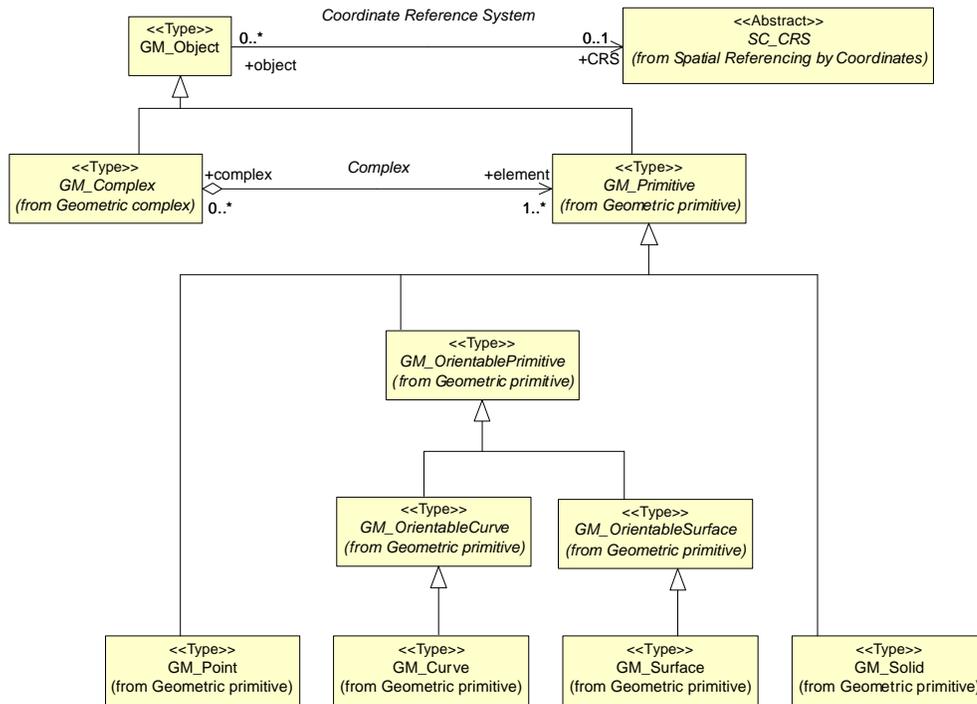

Figure 13

**Figure 14**

The mapping of the different classes to the GML Schemas is explained in the subsequent sections showing details of the class hierarchy.

“GM\_Object” is represented by the “\_Geometry” object element, the “CRS” role is represented by the “srsName” property.

Differences are:

- The “\_Geometry” element can carry additional properties: an optional “description” element, zero or more “name” elements and an optional “gml:id” attribute.
- The “\_Geometry” element is abstract.

### D.2.2.3 Geometry primitive

The following UML class diagrams illustrate the profile of the “Geometry root” package (compare with figures 7 to 13 of ISO 19107).

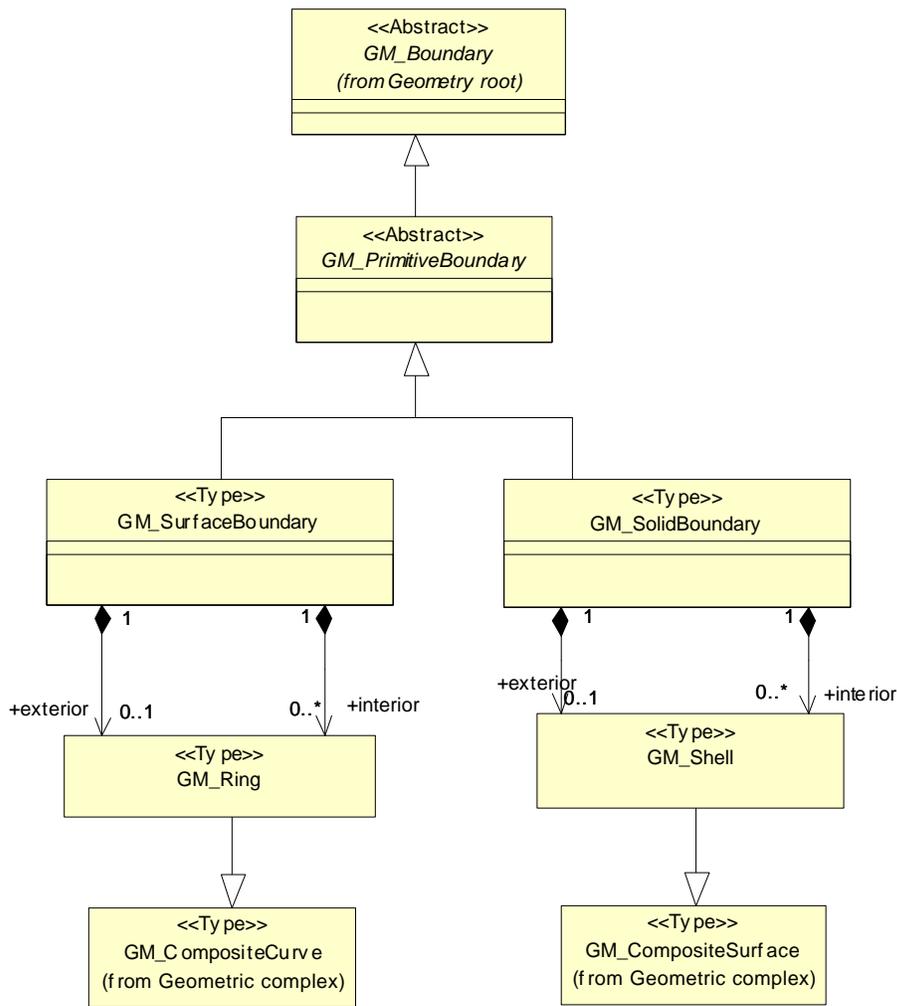

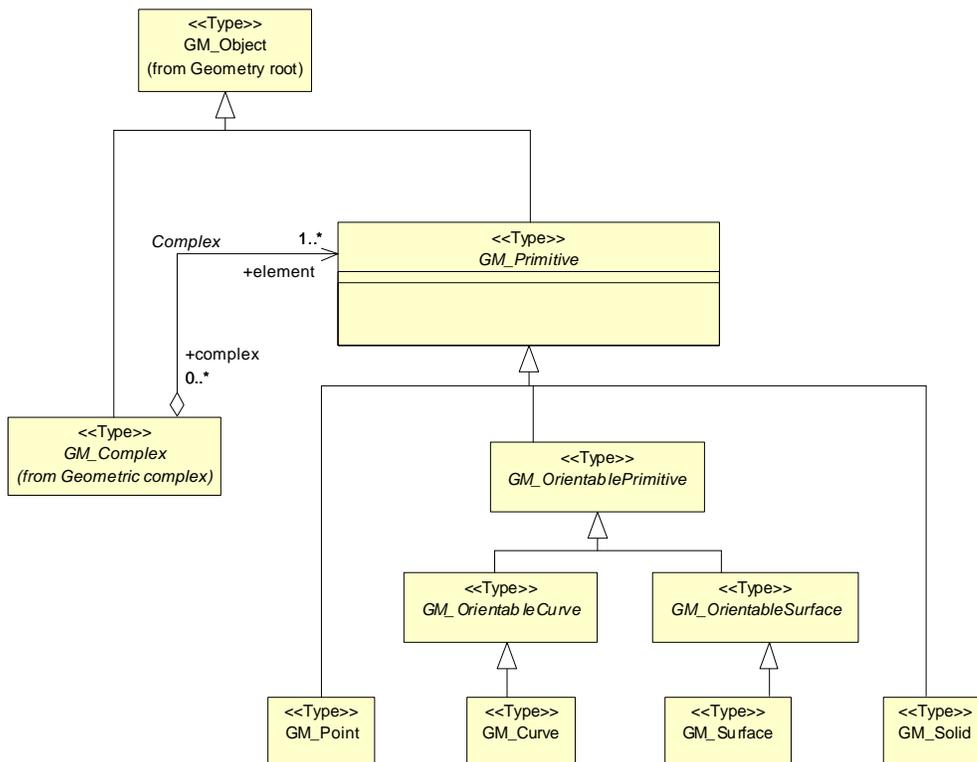

Figure 15

The boundary classes from ISO 19107 are not represented explicitly in GML. In ISO 19107 the boundary types are usually the return value of an operation “boundary()”. As the boundary of all surface (patches) or solids needs to be represented in GML explicitly as properties, the exterior and interior properties have been defined in GML directly as properties of the surface (patch) or solid.

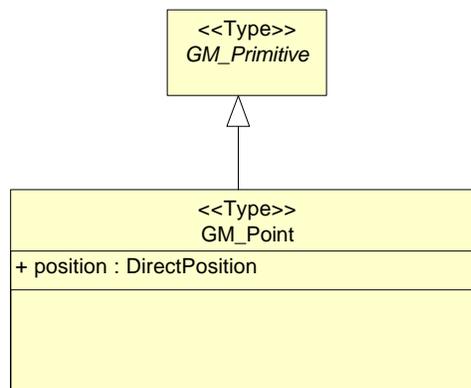

“GM\_Ring” is represented by the “Ring” object element. While a “Ring” is not substitutable for a “CompositeCurve” in GML it is structurally identical to a composite curve.

“GM\_Shell” is also not explicitly represented in GML by its own object element, but a “\_Surface” object element (which can be composite surface) is used instead.

**Figure 16**

“GM\_Primitive” is represented by the “\_GeometricPrimitive” object element (both are abstract). The “complex” role is not navigable in GML.

**Figure 17**

“GM\_Point” is represented by a “Point” object element in GML. The “position” attribute can alternatively be represented by a “pos” property (the type of the value is “DirectPosition”) or a “coordinates” property (the type of the value is “Coordinates”, see below).

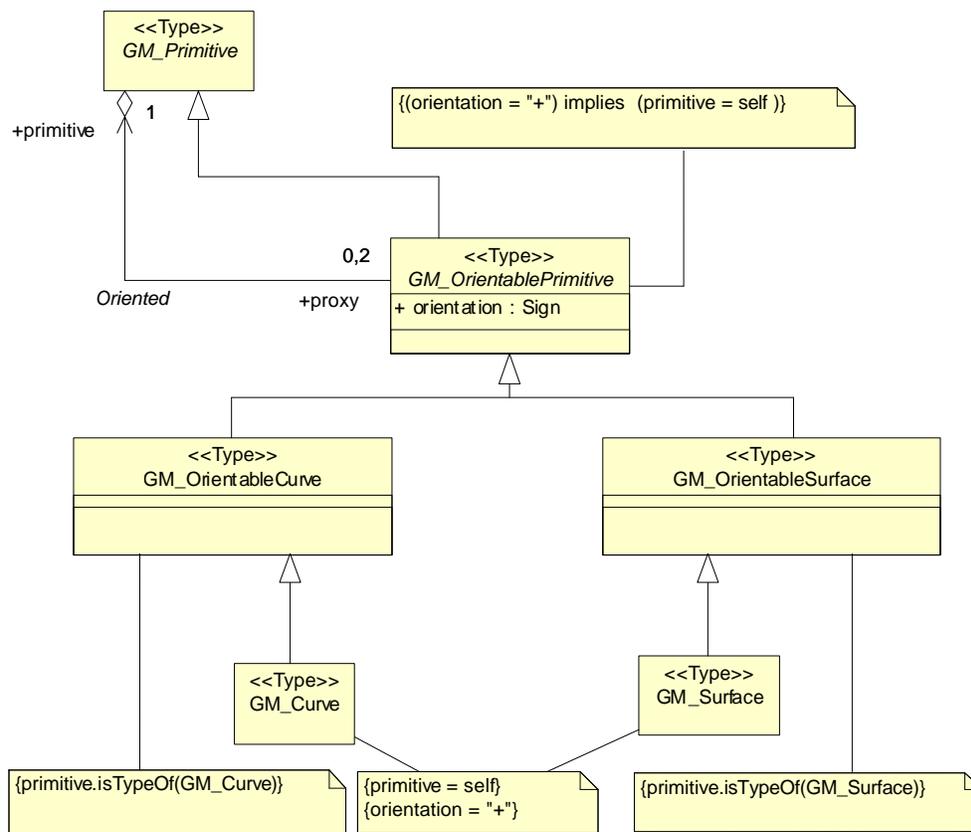

Figure 18

“GM\_Curve” is represented by the “Curve” object element in GML. The orientation is not an explicit property of a “Curve” and is implicitly fixed to “+”.

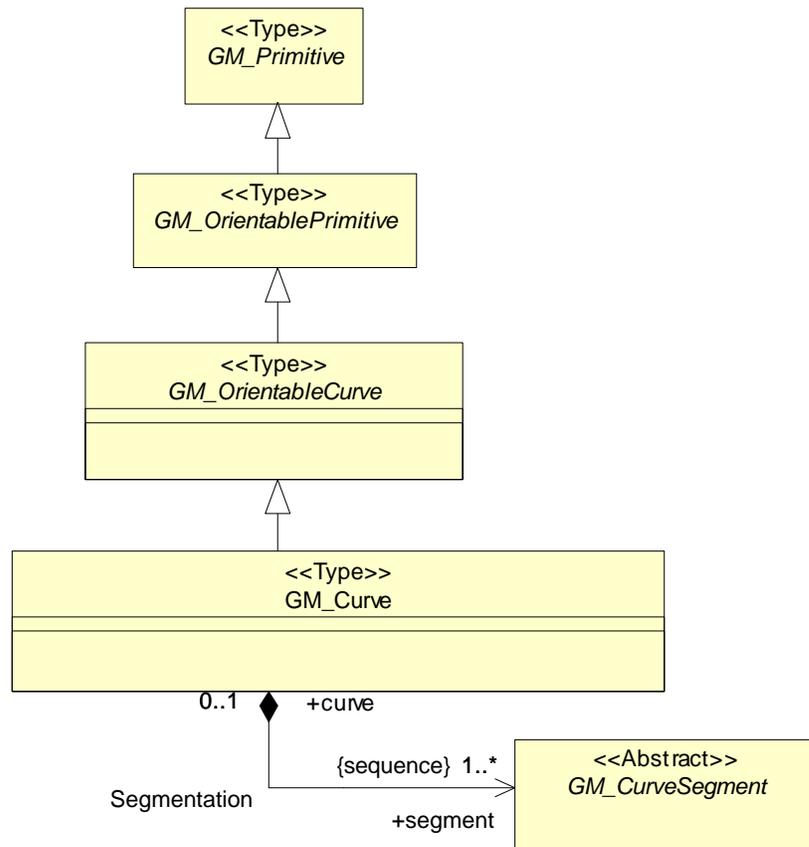

“GM\_OrientableCurve” is represented by the “OrientableCurve” object element in GML. The “primitive” role is represented by the “baseCurve” property.

“GM\_Surface” is represented by the “Surface” object element in GML. The orientation is not an explicit property of a “Surface” and is implicitly fixed to “+”.

“GM\_Orientable Surface” is represented by the “OrientableSurface” object element in GML. The “primitive” role is represented by the “baseSurface” property.

To enable that “CompositeCurve” may be used in GML where in general a geometric primitive is expected, an abstract (and propertyless) object element “\_Curve” has been introduced and can be substituted by either “Curve”, “OrientableCurve” or “CompositeCurve”. The same mechanism is used with surfaces and solids. As a result, the “GM\_OrientablePrimitive” class is not mapped to GML explicitly, however as this type is not instantiable, this does not impose any restrictions.

NOTE This mapping is a consequence of the fact that the spatial schema uses multiple inheritance to express that a composite geometry, which by definition is a complex geometry, can also be viewed as a geometric primitive. Since XML Schema is not capable of multiple inheritance (or more precisely: derivation from multiple types), the abstract object elements “\_Curve”, “\_Surface” and “\_Solid” have been introduced in GML to allow that both “true” geometric primitives (e.g. “Curve”) and composite geometries (e.g. “CompositeCurve”) can be in a common substitution group, although both are structurally different.

**Figure 19**

As discussed above, “GM\_Curve” is represented by the “Curve” object element in GML. The “segment” role is represented as an array property “segments” in GML.

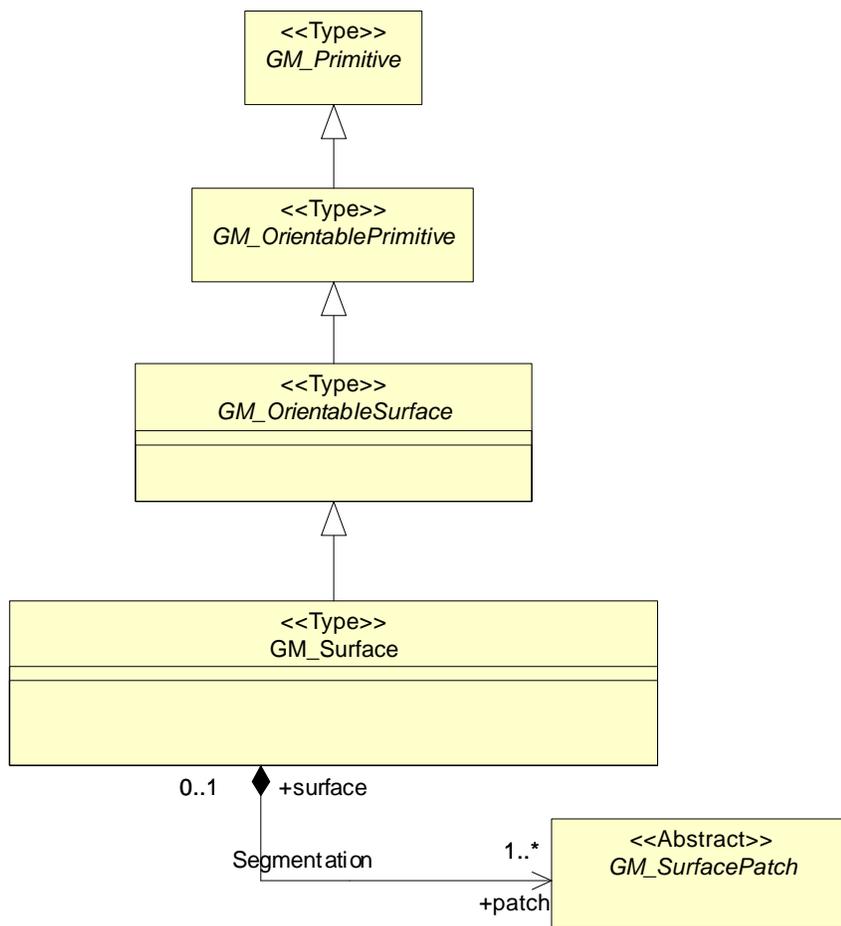

Figure 20

As discussed above, “GM\_Surface” is represented by a “Surface” object element in GML. The “patch” role is represented as an array property “patches” in GML.

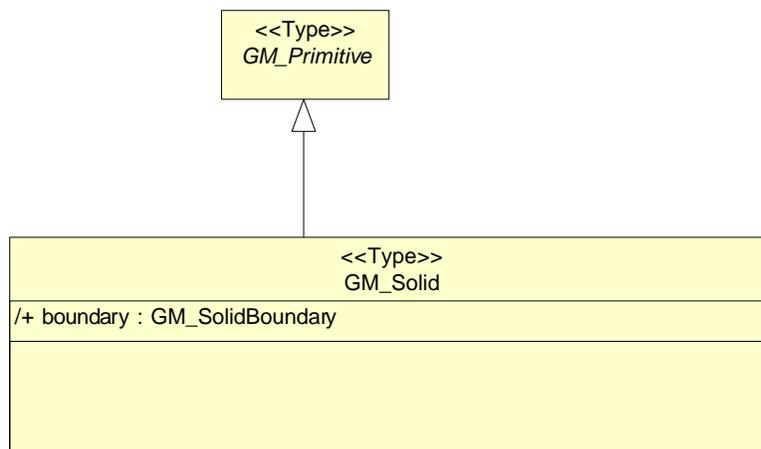

Figure 21

“GM\_Solid” is represented by a “Solid” object element in GML. The boundary of a Solid is directly expressed by “exterior” and “interior” properties of the solid as discussed above.

#### D.2.2.4 Coordinate Geometry

The following UML class diagrams illustrate the profile of the Coordinate Geometry package (compare with figures 14 to 21 of ISO 19107).

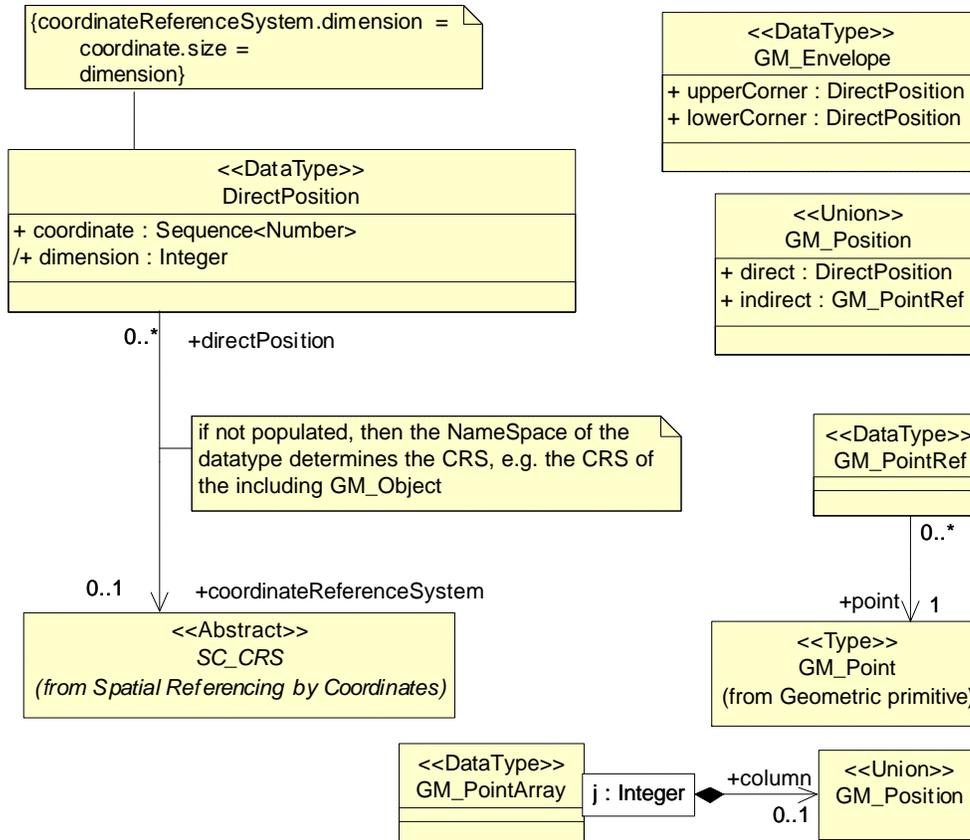

Figure 22

“DirectPosition” is in GML represented as a type with simple content where the “coordinate” attribute is mapped to a list of doubles. The “coordinateReferenceSystem” role is represented by a “srsName” attribute property and “dimension” is represented by an optional attribute property of the same name (type is positiveInteger).

“GM\_Position” is mapped to a choice between a “pos” property (which is of type “DirectPosition”) and a “pointProperty” property (which is “Point”-valued). A “GM\_PointArray” is represented as a similar choice element, but with appropriate settings for minimum and maximum occurrences.

A single “GM\_Position” or a “GM\_PointArray” can alternatively be represented by a “coordinates” property (the type of the value is “Coordinates” which is a type with simple content that represents a list of coordinates encoded as a string).

“GM\_Envelope” is represented as the “Envelope” object element in GML. The two attributes “upperCorner” and “lowerCorner” are mapped to properties of the same name.

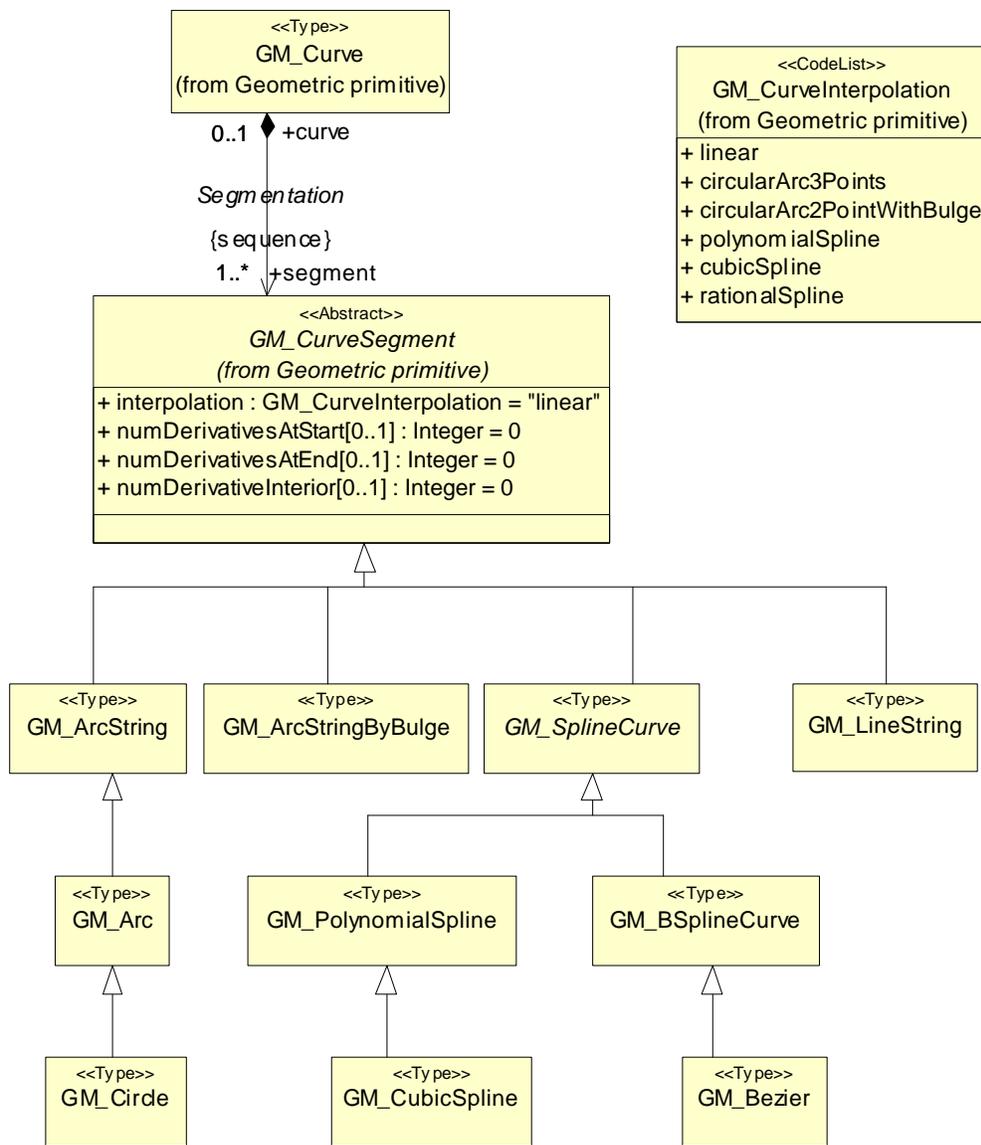

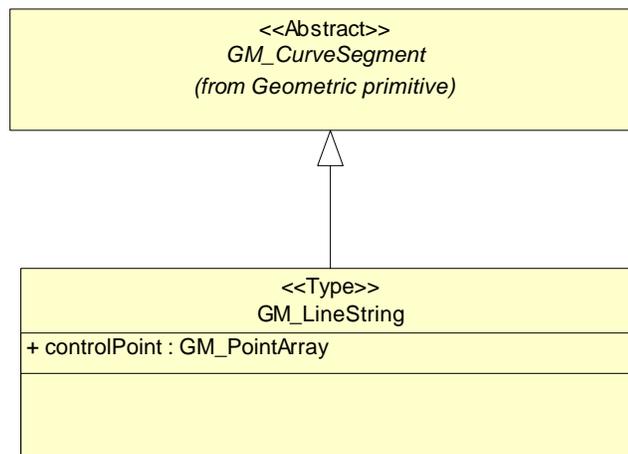

Figure 23

“GM\_CurveSegment” is represented in GML by the “\_CurveSegment” object element (both are abstract). The three “numDerivatives...” attributes are mapped to properties with the same definition. The “interpolation” attribute is not defined in “\_CurveSegment”, but is defined (and set with appropriate initial values) in the instantiable subtypes.

GML currently supports a subset of all defined curve segments of ISO 19107.

Most subtypes of “GM\_CurveSegment” carry a “controlPoint” attribute that is represented in GML by the choice element as described above (see discussion of the representation of a GM\_PointArray).

The code list “GM\_CurveInterpolation” has been mapped to GML as if it would be an enumeration, i.e. no additional values are allowed beside the predefined values in the GML Schema.

**Figure 24**

“GM\_LineString” is represented by the “LineStringSegment” object element. The “Segment” suffix is appended to the name in GML, because the name “LineString” is already reserved for another object element in GML (see below).

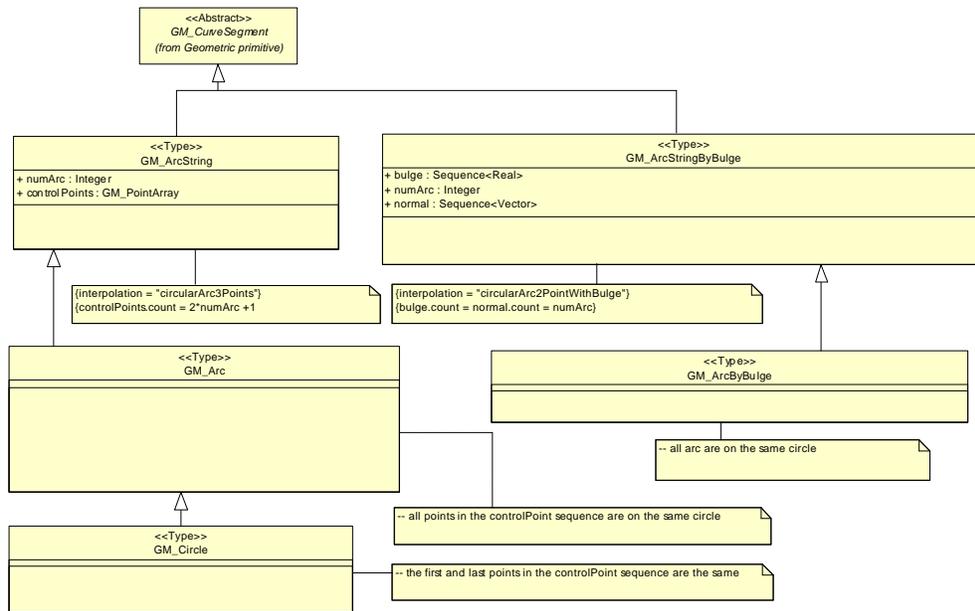

Figure 25

The curve segment types are mapped to object elements in GML with the same name (but without the “GM\_” prefix) and the same set of properties.

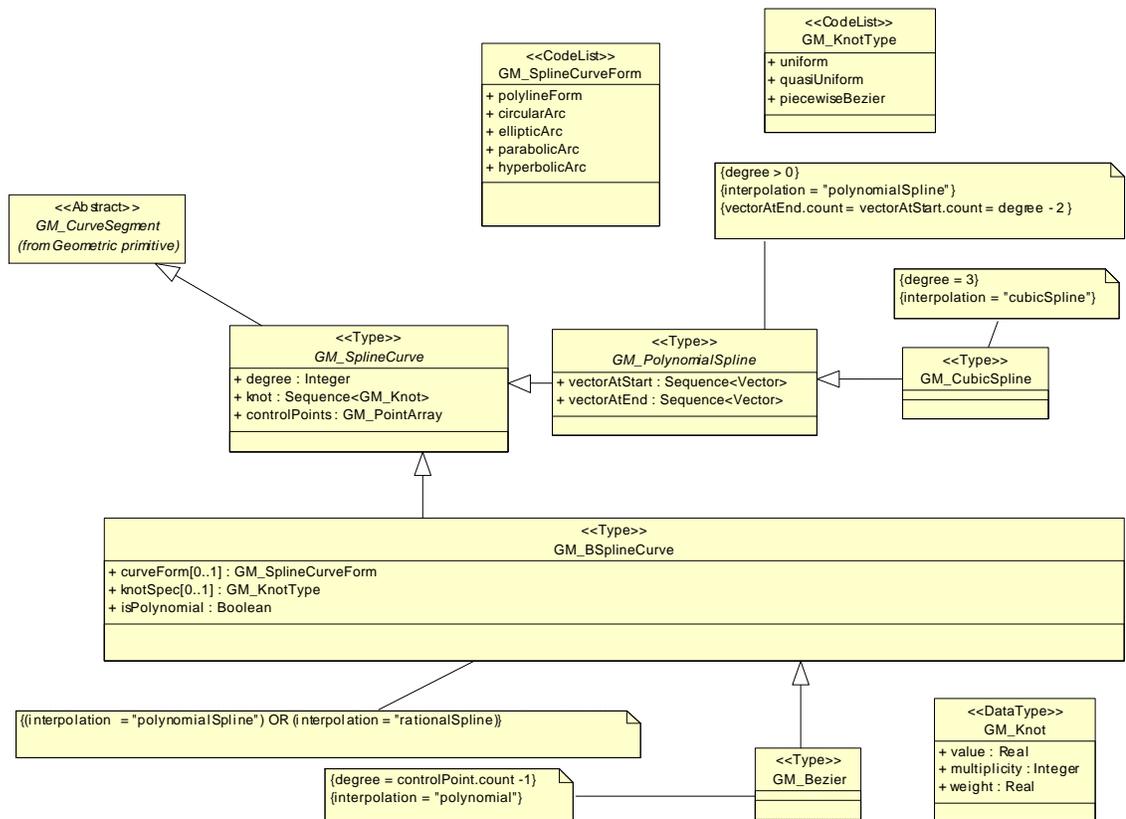

Figure 26

Again, these curve segment types are mapped to object elements in GML with the same name (but without the “GM\_” prefix<sup>3</sup>) and the same properties<sup>4</sup>. The properties of the curve segment objects in GML have been specified taking the OCL constraints into account.

The code list “GM\_KnotType” has been mapped to GML as if it would be an enumeration, i.e. no additional values are allowed beside the predefined values in the GML Schema.

<sup>3</sup> However, “GM\_BSplineCurve” is represented by “BSpline”, i.e. without the “Curve” suffix.

<sup>4</sup> The “knotSpec” attribute has been renamed to “knotType” in GML.

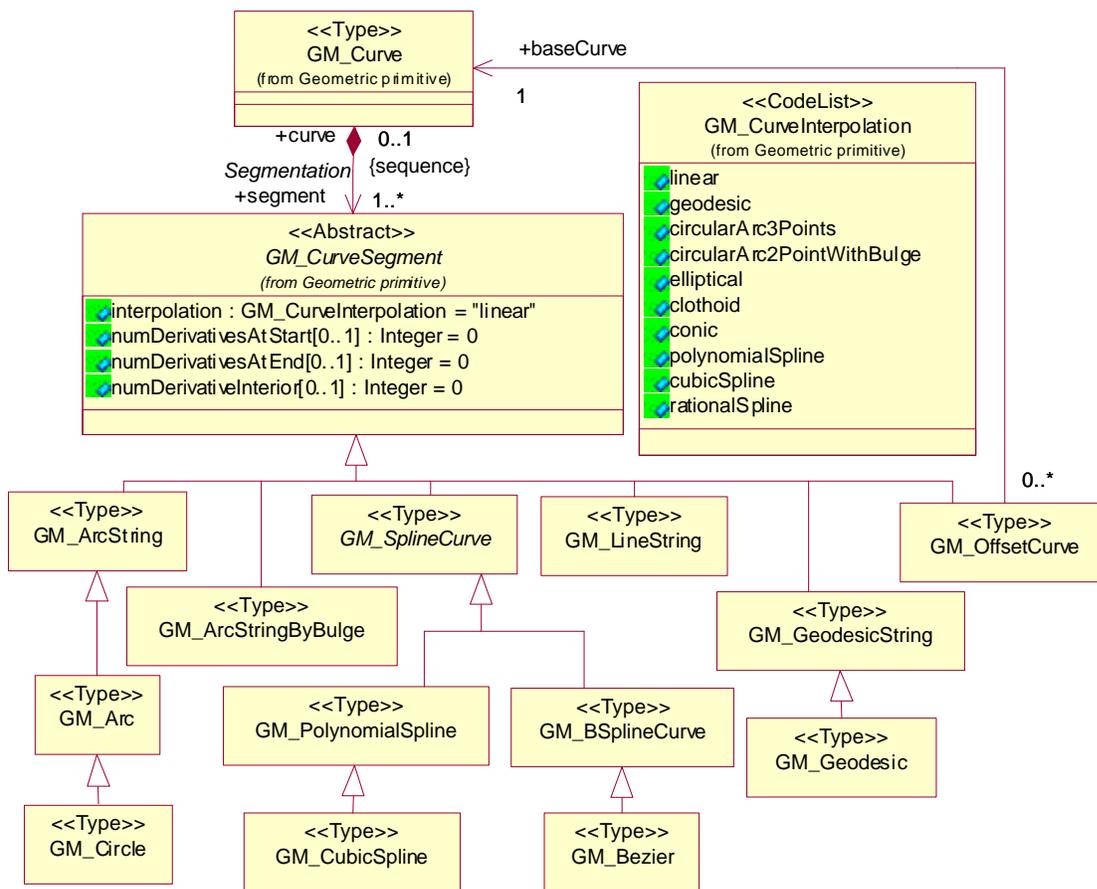

Figure 27

“GM\_OffsetCurve” class is represented in GML by the “OffsetCurve” object element. The object carries the same semantic interpretation as the class. The baseCurve property has been renamed to offsetBase.

“GM\_AffinePlacement” is represented in GML by the “AffinePlacement” object element.

“GM\_GeodesicString” is represented in GML by the “GeodesicString” object element.

“GM\_Geodesic” is represented in GML by the “Geodesic” object element.

“GM\_Clothoid” is represented in GML by the “Clothoid” object element.

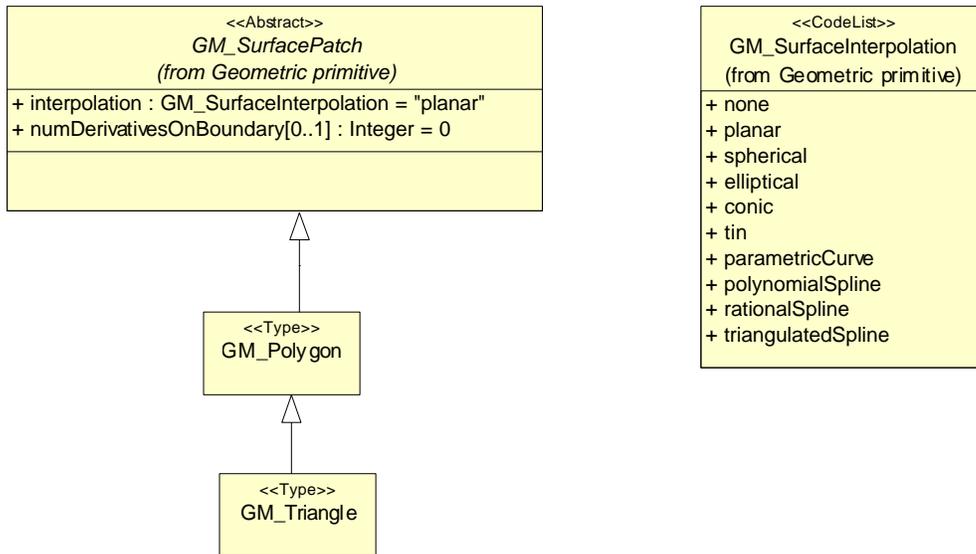

Figure 28

“GM\_SurfacePatch” is represented in GML by the “\_SurfacePatch” object element (both are abstract). The “numDerivativesOnBoundary” attribute is currently not explicitly mapped in GML as only planar interpolation is currently supported in GML. The “interpolation” attribute is not defined in “\_SurfacePatch”, but it is defined (and set with appropriate initial values) in the instantiable subtypes.

GML currently supports a subset of all defined surface types and surface patch types of ISO 19107.

The code list “GM\_SurfaceInterpolation” has been mapped to GML as if it would be an enumeration, i.e. no additional values are allowed beside the predefined values in the GML Schema.

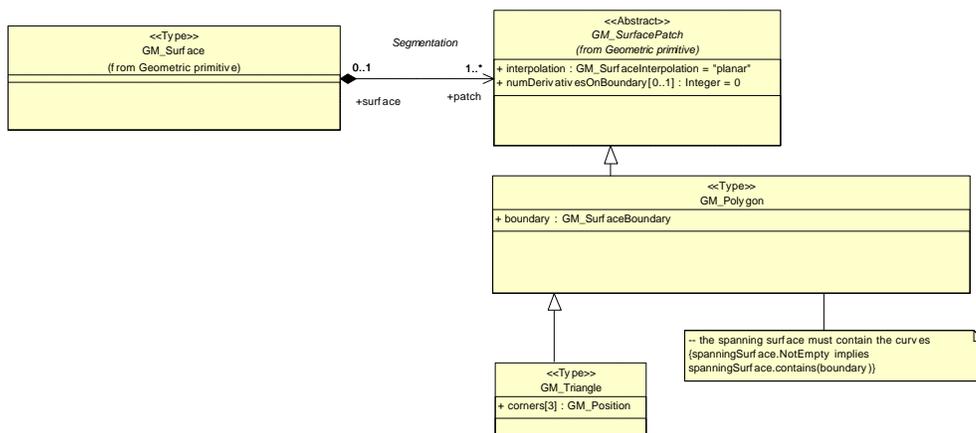

Figure 29

“GM\_Polygon” is represented by the “PolygonPatch” object element. The “boundary” attribute is directly expressed by “exterior” and “interior” properties of the “PolygonPatch”.

The “Patch” suffix has been appended to the name in GML, because the name “Polygon” is already reserved for another object element in GML (see below).

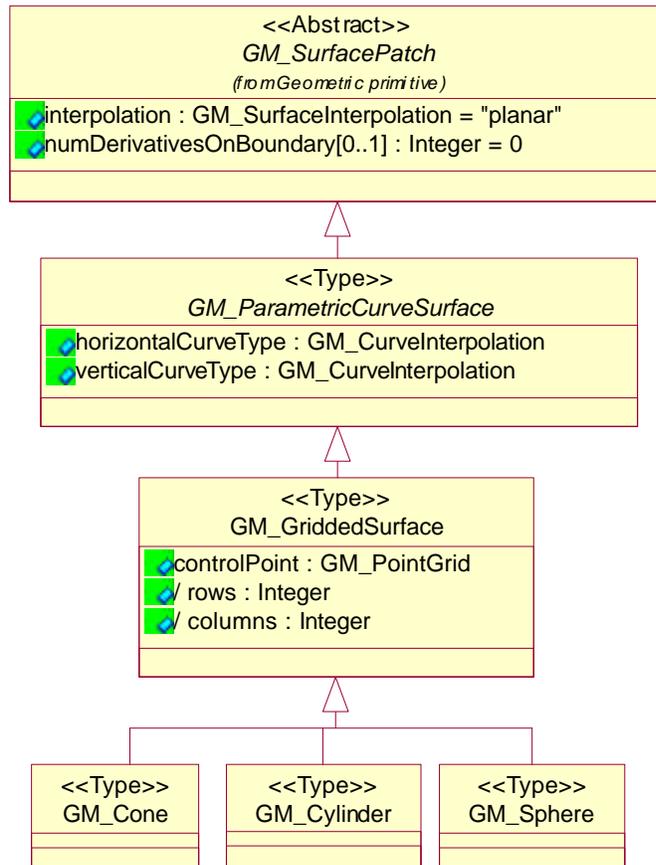

Figure 30

“GM\_PointGrid” is represented in GML by the “PointGrid” group.

“GM\_ParametricCurveSurface” is represented in GML by the “\_ParametricCurveSurface” object element (both are abstract).

“GM\_GriddedSurface” is represented in GML by the “\_GriddedSurface” object element (both are abstract).

“GM\_Cone” is represented in GML by the “Cone” object element.

“GM\_Cylinder” is represented in GML by the “Cylinder” object element.

“GM\_Sphere” is represented in GML by the “Sphere” object element.

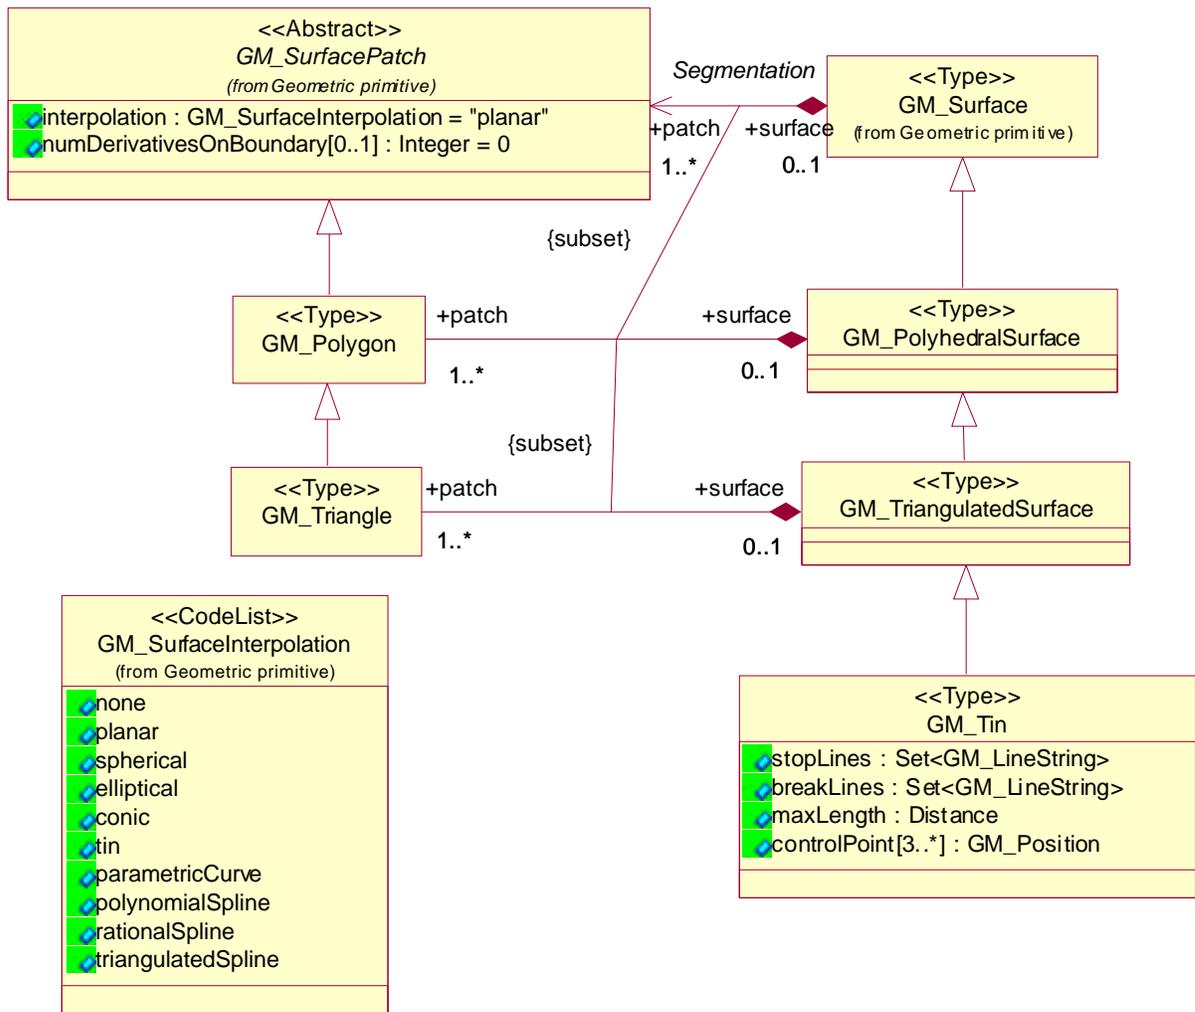

Figure 31

“GM\_PolyhedralSurface” is represented in GML by the “PolyhedralSurface” object element.

“GM\_TriangulatedSurface” is represented in GML by the “TriangulatedSurface” object element.

“GM\_Tin” is represented in GML by the “Tin” object element.

#### D.2.2.5 Geometry aggregates

The following UML class diagrams illustrate the profile of the “Geometry root” package (compare with figure 24 of ISO 19107).

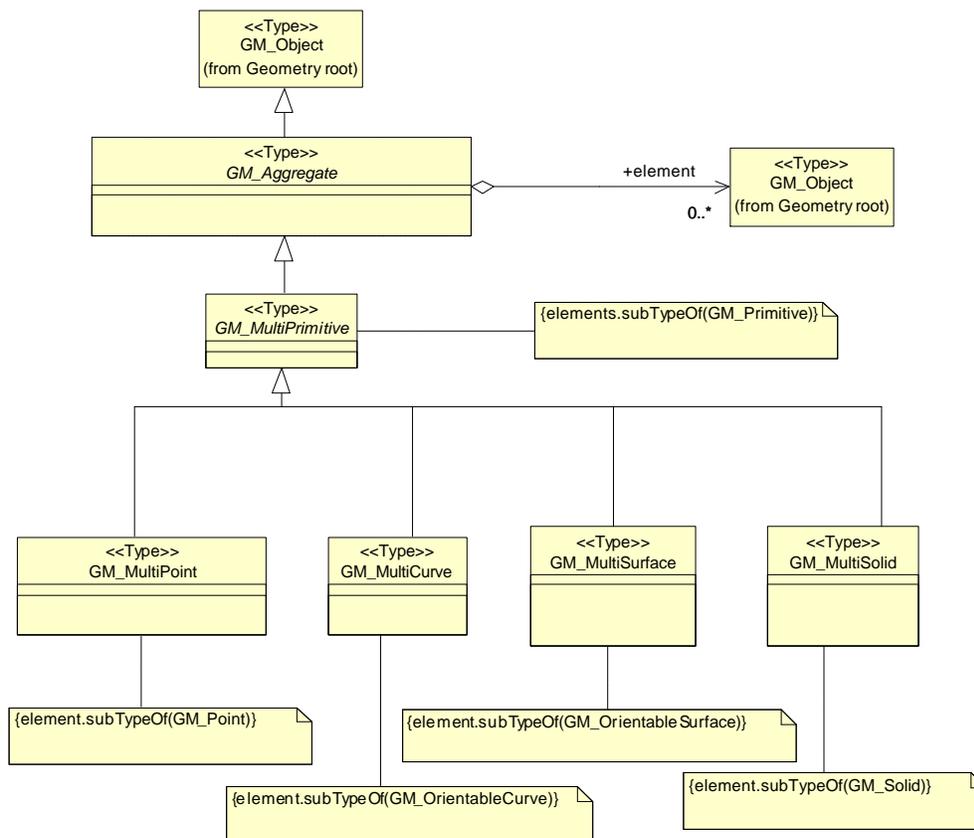

Figure 32

“GM\_Aggregate” is represented by the “\_GeometricAggregate” object element (both are abstract). The “element” role is in GML instantiated in the instantiable subtypes. The general pattern is that two properties are defined, one is a regular association property and the other an array association property. The property names are “xMember” and “xMembers” respectively where the “x” is replaced by “point”, “curve”, “surface” or “solid” depending on the elements of the collection. This represents the OCL-constraints for type safety.

“GM\_MultiPoint” is represented by the “MultiPoint” object element in GML.

“GM\_MultiCurve” is represented by the “MultiCurve” object element in GML.

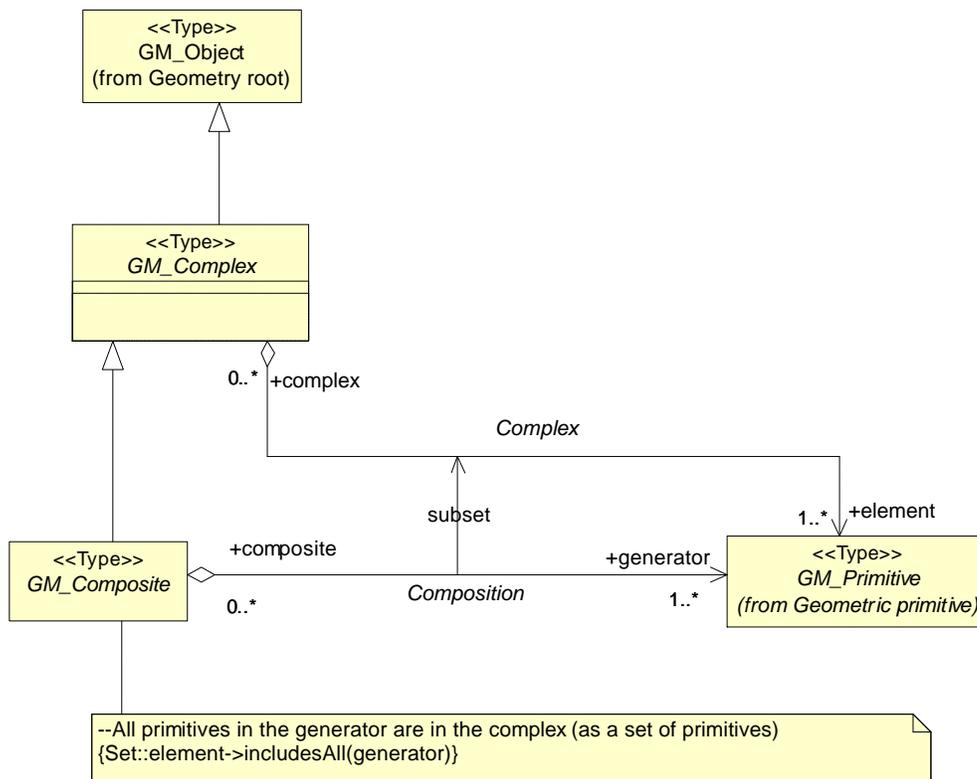

“GM\_MultiSurface” is represented by the “MultiSurface” object element in GML.

“GM\_MultiSolid” is represented by the “MultiSolid” object element in GML.

“GM\_MultiPrimitive” is not explicitly represented in GML.

### D.2.2.6 Geometry complex

The following UML class diagrams illustrate the profile of the “Geometry root” package (compare with figures 25 to 30 of ISO 19107).

**Figure 33**

“GM\_Complex” is represented by the “GeometricComplex” object element. The “element” role is mapped to a property of the same name in GML.

“GeometricComplex” can be instantiated (unlike “GM\_Complex” which is abstract).

The fact that the composite geometry types are subtypes of “GM\_Complex” is represented in GML by the fact that every association property which takes a “GeometricComplex” accepts also one of the composites (due to a choice element in “GeometricComplexPropertyType”). This special mapping to XML Schema was necessary, because multiple inheritance, used in ISO 19107 to express the “dualism” of the composite geometries, is not supported by the derivation mechanism of XML Schema.

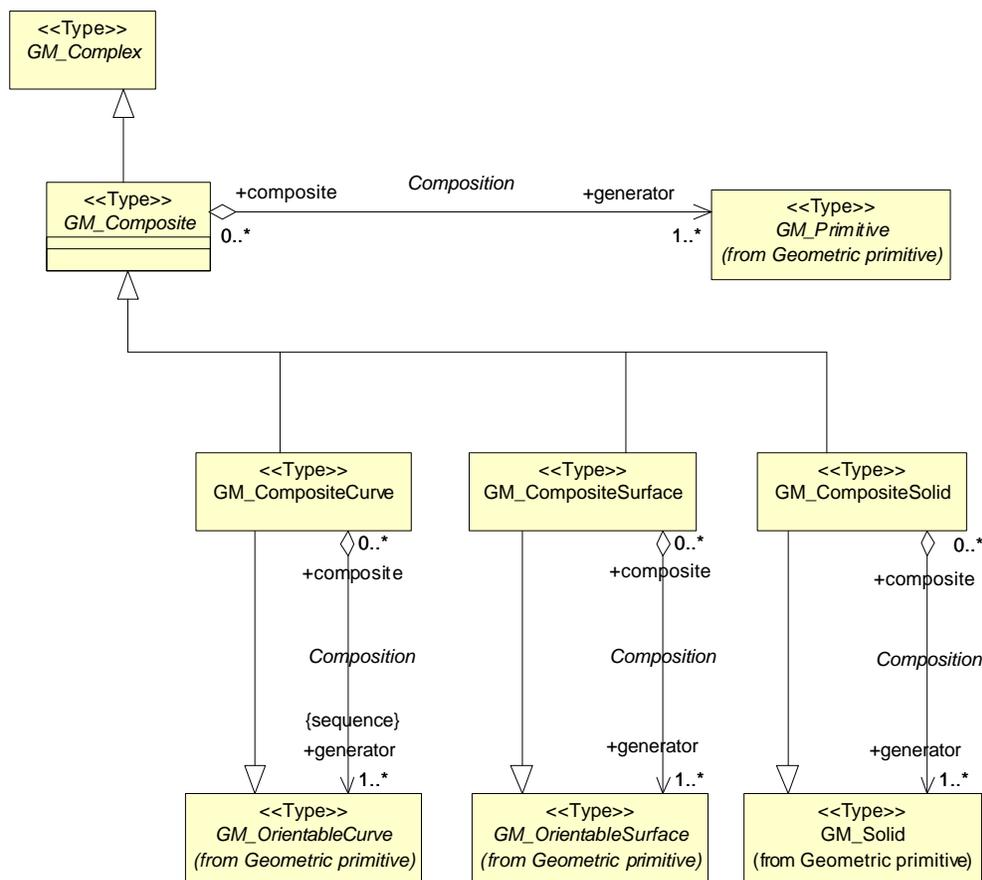

Figure 34

“GM\_Composite” is not explicitly represented by an object element in GML. However, the subtypes “GM\_CompositeCurve”, “GM\_CompositeSurface” and “GM\_CompositeSurface” are represented in GML by object elements of the same name (without the “GM\_” prefix). The “generator” role is in GML instantiated in these subtypes by an association property with the name “xMember” where the “x” is replaced by “curve”, “surface” or “solid” depending on the elements of the collection.

### D.2.2.7 Conformance

The rules governing conformance of a profile of ISO 19107 are described in chapter 2 and annex A of ISO DIS 19107. Concerning the three criteria defined in chapter 2, GML geometry covers the following levels:

Data Complexity:

- Geometric primitives
- Geometric complexes

Dimensionality:

- 0-, 1-, 2- and 3-dimensional objects

Functional Complexity:

- Data types only

Thus, the relevant conformance clauses of ISO 19107 are:

- A.1.1.1 - A.1.1.4
- A.2.1.1 - A.2.1.3

The conditions of these conformance clauses are met.

Note that derived attributes are treated as operations and it is assumed that the derived attributes in the aggregate geometries will be derived from the data by the application handling the GML instances.

A GM\_CompositePoint is represented by a “Point” object element in GML. The value of the “generator” association role is the same object, i.e. the “Point” object itself.

## D.2.3 ISO 19107 Spatial Schema (Topology)

### D.2.3.1 Overview

The following additional changes have been applied to the topology package of ISO 19107.

**Table 11**

Change	Explanation
TP_Complex: association „isMaximal()“ added as a derived attribute	The information was otherwise not accessible by means of predefined data structures of TP_Complex. The attribute shall be defined as a derived attribute representing the result of the “isMaximal()” operation as defined in ISO 19107.
TP_Object has been changed from an interface class to type class (however without any properties) and the Realization relationships from TP_Primitive and TP_Complex to TP_Complex has been changed to Specialization relationships.	Maintaining TP_Object as a root for the different topological subtypes makes to mapping to GML clearer.
The optional association “Realization” between TP_Complex and GM_Complex has been deleted.	The realization can be derived from the realization of the primitives contained in the topological complex.
The “maximalComplex” role has been deleted from TP_Primitive.	Currently not supported in GML
TP_Boundary and subtypes as well as TP_Ring and TP_Shell have been deleted.	Only used in operations

### D.2.3.2 Topology root

The following UML class diagrams illustrate the profile of the “Topology root” package (compare with figures 32 to 33 of ISO 19107).

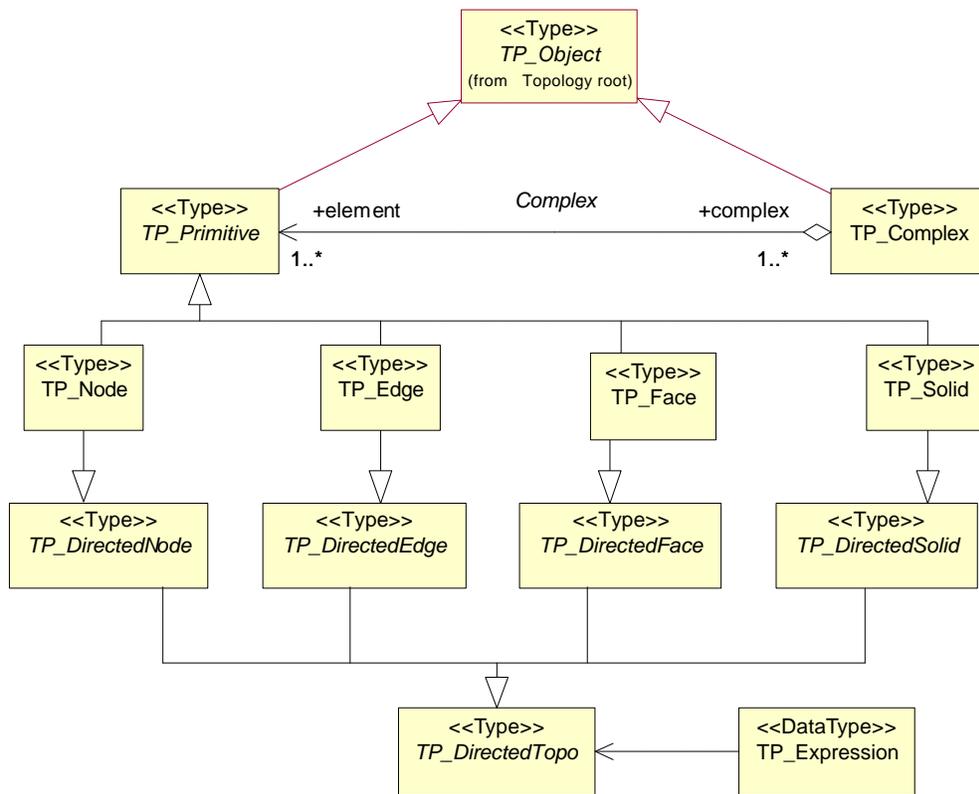

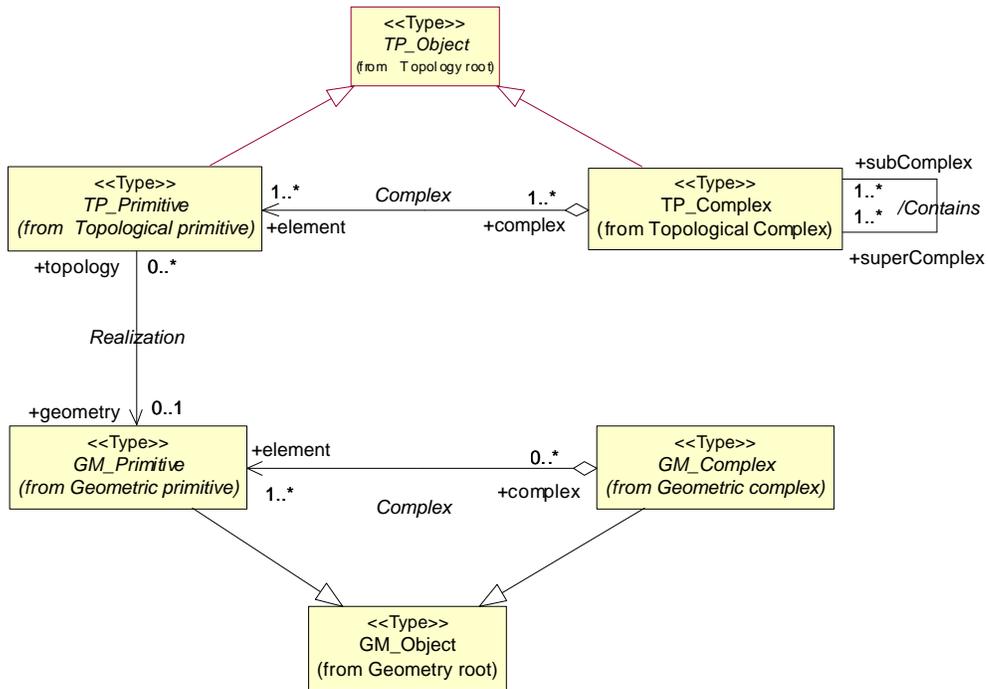

Figure 35

**Figure 36**

The mapping of the different classes to the GML Schemas is explained in the subsequent sections showing details of the class hierarchy.

“TP\_Object” is represented by the “\_Topology” object element. The “\_Topology” element may carry additional properties: an optional “description” element, zero or more “name” elements and an optional “gml:id” attribute.

### D.2.3.3 Topology primitive

The following UML class diagrams illustrate the profile of the “Topology root” package (compare with figures 35 to 45 of ISO 19107).

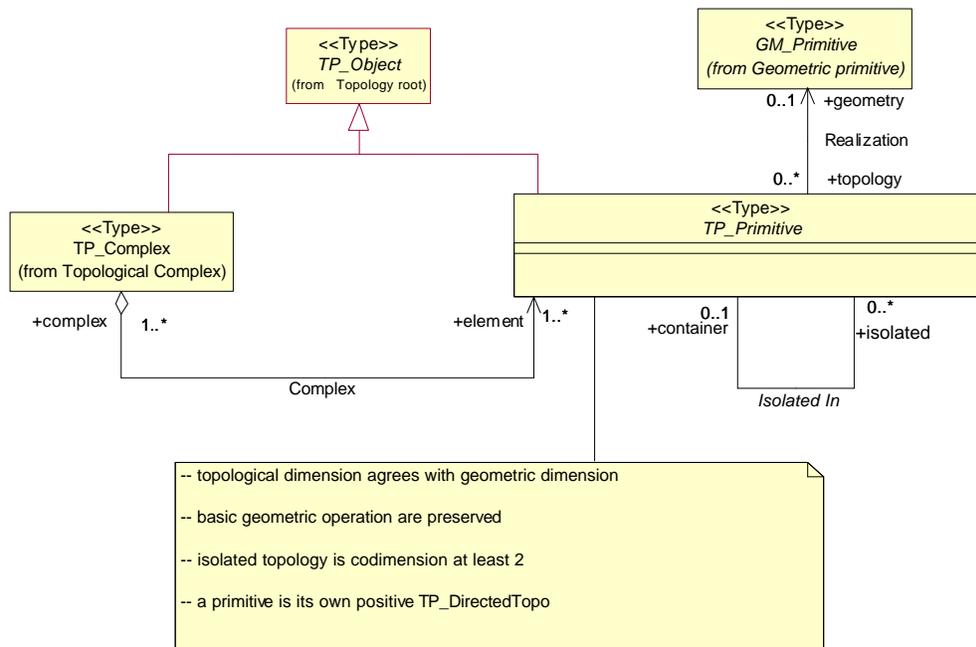

Figure 37

“TP\_Primitive” is represented by the “\_TopoPrimitive” object element.

The “geometry” role is instantiated in the instantiable subtypes. This allows to control the geometry types at the other association end (dimensionality constraint): “pointProperty”, “curveProperty”, “surfaceProperty” and “solidProperty” respectively.

The “isolated” and “container” roles are represented as properties in “\_TopoPrimitive”.

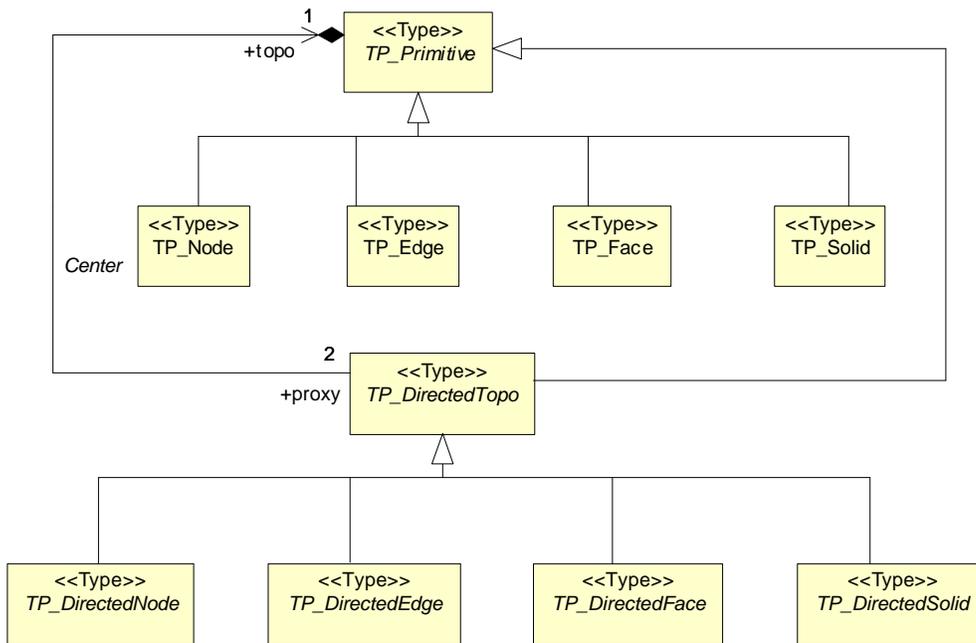

Figure 38

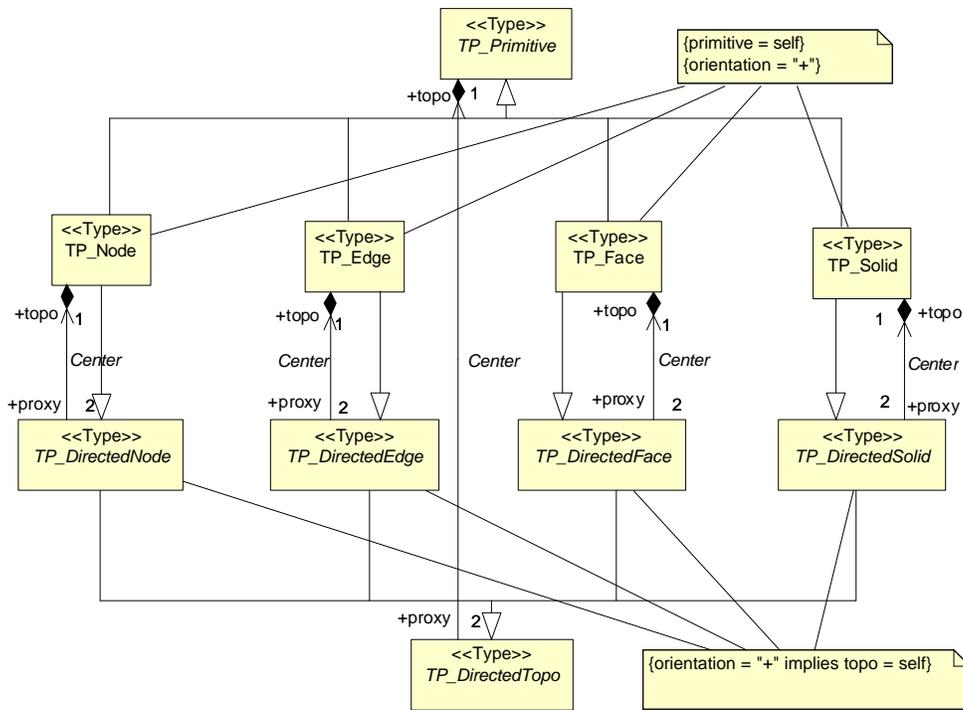

Figure 39

“TP\_Node” is represented by the “Node” object element in GML.

“TP\_Edge” is represented by the “Edge” object element in GML.

“TP\_Face” is represented by the “Face” object element in GML.

“TP\_Solid” is represented by the “TopoSolid” object element in GML (the name “Solid” is already used for the 3-dimensional geometry primitive).

“TP\_DirectedTopo” is not explicitly represented in GML, only its instantiable subtypes. A notable difference is that although the directed topology types are modelled as types they are represented as properties with an “orientation” attribute in GML.

“TP\_DirectedNode” is represented by the “directedNode” property element in GML. The “topo” role is represented directly by the “Node” object element.

“TP\_DirectedEdge” is represented by the “directedEdge” property element in GML. The “topo” role is represented directly by the “Edge” object element.

“TP\_DirectedFace” is represented by the “directedFace” property element in GML. The “topo” role is represented directly by the “Face” object element.

“TP\_DirectedSolid” is represented by the “directedTopoSolid” property element in GML. The “topo” role is represented directly by the “TopoSolid” object element.

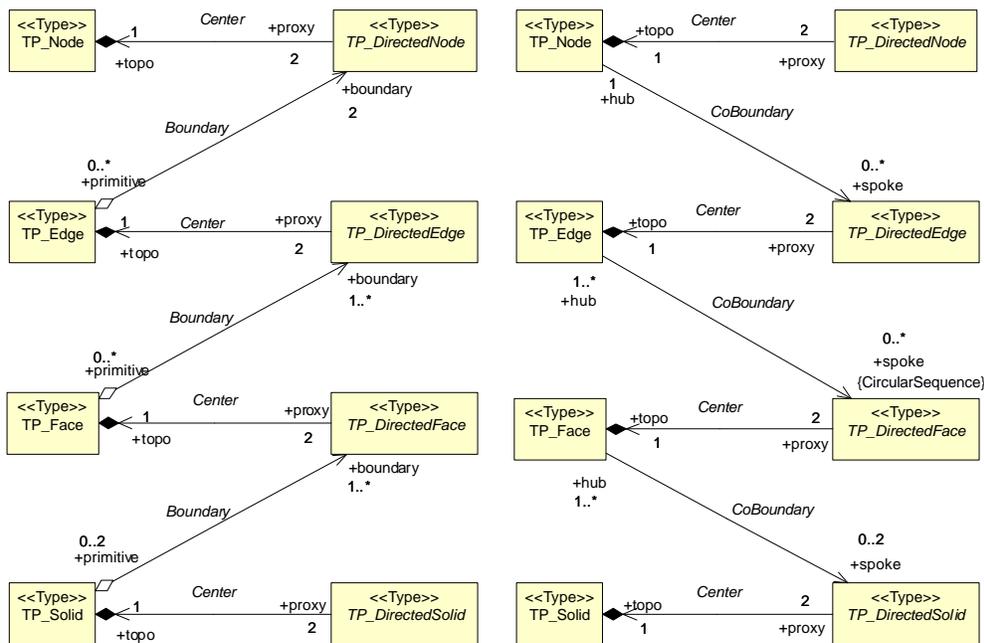

Figure 40

The mapping of the “topo” role is already discussed above.

The “spoke” role is represented in GML by “directed Edge”, “directedFace” and “directedTopoSolid” properties respectively.

The “boundary” role is represented in GML by “directed Node”, “directedEdge” and “directedFace” properties respectively.

#### D.2.3.4 Topology complex

The following UML class diagrams illustrate the profile of the “Topology complex” package (compare with figure 46 of ISO 19107).

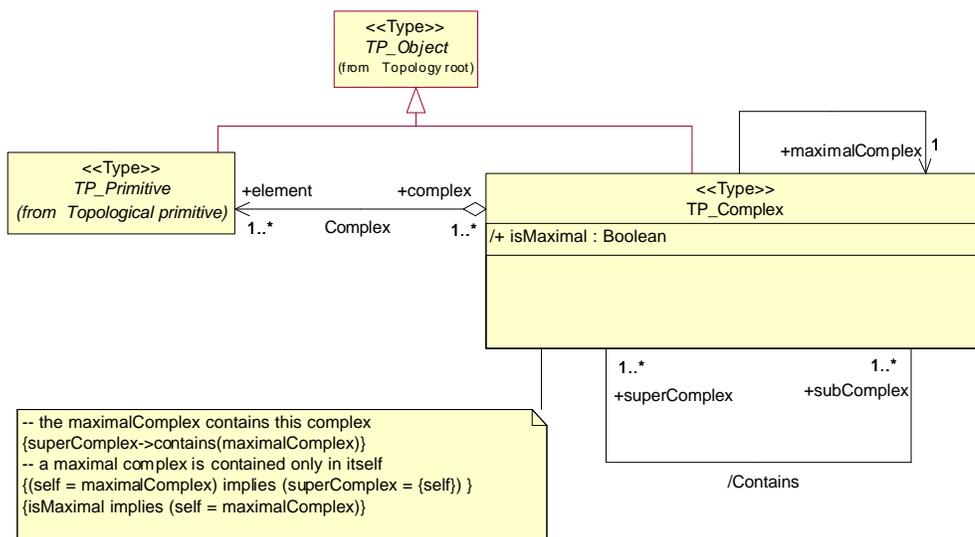

Figure 41

“TP\_Complex” is represented by the “TopoComplex” object element.

The “element” role is mapped to two properties – one regular association property “topoPrimitiveMember” and one array association property “topoPrimitiveMembers”.

The “subComplex” and “superComplex” roles are represented as association properties of the same name. The minimum multiplicity, however, is “0” for both properties in GML instead of “1”. This reflects that it is not required that this property is represented explicitly in a GML instance (note that it is a derived association).

The “maximalComplex” role is represented as an association property of the same name in GML.

#### D.2.3.5 Conformance

The rules governing conformance of a profile with ISO 19107 are described in chapter 2 and annex A of ISO DIS 19107. Concerning the three criteria defined in chapter 2, GML topology covers the following levels:

Data Complexity:

- Topological complexes
- Topological complexes with geometric realizations

Dimensionality:

- 0-, 1-, 2- and 3-dimensional objects

Functional Complexity:

- Data types only

Thus, the relevant conformance clauses of ISO 19107 are:

- A.3.1.1 - A.3.1.3
- A.4.1.1 - A.4.1.3

The conditions of these conformance clauses are met.

Note that the association “Realization” between TP\_Complex and GM\_Complex is not an explicit part of the profile, because the geometrical realization of the topological complex can be derived from the geometrical realization of the topological primitives.

## D.2.4 ISO 19108 Temporal Schema

### D.2.4.1 Overview

The GML temporal schemas provides an implementation of clauses 5.2 - 5.4 of ISO 19108:2002.

The following changes have been applied to the packages of ISO 19108.

**Table 12**

	Change	Explanation
1	The <i>beginning</i> and <i>ending</i> associations are implemented as unidirectional from TM_Period to TM_Instant	Maintaining bi-directional pointers deemed unnecessary in a static data encoding
2	The <i>beginning</i> and <i>ending</i> associations from TM_Period are implemented as a choice of (a UML association with TM_Instant or a UML attribute of type TM_Position)	Allows a more compact encoding of the same information when a TM_Instant object with identity is not required
3	The <i>termination</i> and <i>initiation</i> associations are implemented as unidirectional from TM_Edge to TM_Node	Maintaining bi-directional pointers deemed unnecessary in a static data encoding
4	The <i>realization</i> associations are implemented as unidirectional from TM_Instant and TM_Period to TM_Node and TM_Edge respectively	Maintaining bi-directional pointers deemed unnecessary in a static data encoding
5	The <i>basis</i> association is implemented as unidirectional from TM_Calendar to TM_CalendarEra	Maintaining bi-directional pointers deemed unnecessary in a static data encoding
7	The <i>begin</i> and <i>end</i> attributes of TM_OrdinalEra are replaced by associations with TM_Node, with rolenames <i>start</i> and <i>end</i>	Practice in historical and geological sciences is that the termination points of an Ordinal Era are associated with events whose position may not be known precisely. This matches with the concept of of TM_Node whose position is available indirectly.
8	The <i>origin</i> attribute of TM_CoordinateSystem is implemented as choice of (a UML association with TM_Instant or a UML attribute of type TM_Position)	Allows the origin to be specified in terms of an external event.
9	The <i>interval</i> attribute of TM_CoordinateSystem is implemented as TM_Interval Length	Allows the scale to be specified more precisely and flexibly.

NOTE 1 Change 2 takes advantage of the <choice> structure which is provided by the XML Schema implementation language. This supports a more flexible and compact encoding, containing the same information, than would have been gained by mechanical application of the standard encoding rules.

NOTE 2 A change proposal has been submitted regarding ISO 19108 to match the issue identified in change 7.

Of the classes dealing with temporal relationships between features, described in clause 5.5 of ISO 19108:2002, only Feature Succession has been implemented directly. Components corresponding to the other relationships may be defined in GML application schemas, but are not discussed further here.

The mapping of the different classes to the GML Schemas is explained in the subsequent sections showing details of the class hierarchy.

The following UML class diagrams illustrate the profile of the “Temporal Objects” package (compare with figures 2 to 6 and 11 of ISO 19108:2002).

#### D.2.4.2 Temporal Objects

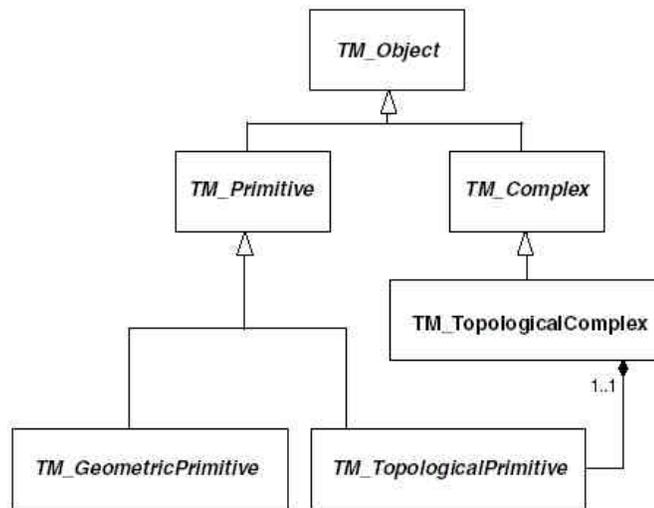

Figure 42 Main hierarchy of temporal objects from ISO 19108:2002

“TM\_Object” is represented by the “\_TimeObject” object element. The “\_TimeObject” element can carry additional properties: an optional “description” element, zero or more “name” elements and an optional “gml:id” attribute. These properties are inherited by all the components that are substitutable for \_TimeObject.

“TM\_Primitive” is represented by the “\_TimePrimitive” object element.

“TM\_GeometricPrimitive” is represented by the “\_TimeGeometricPrimitive” object element.

“TM\_TopologicalPrimitive” is represented by the “\_TimeTopologyPrimitive” object element.

“TM\_Complex” is represented by the “\_TimeComplex” object element.

“TM\_TopologicalComplex” is represented by the “\_TimeTopologyComplex” object element.

D.2.4.3 Concrete Temporal Geometric Primitives

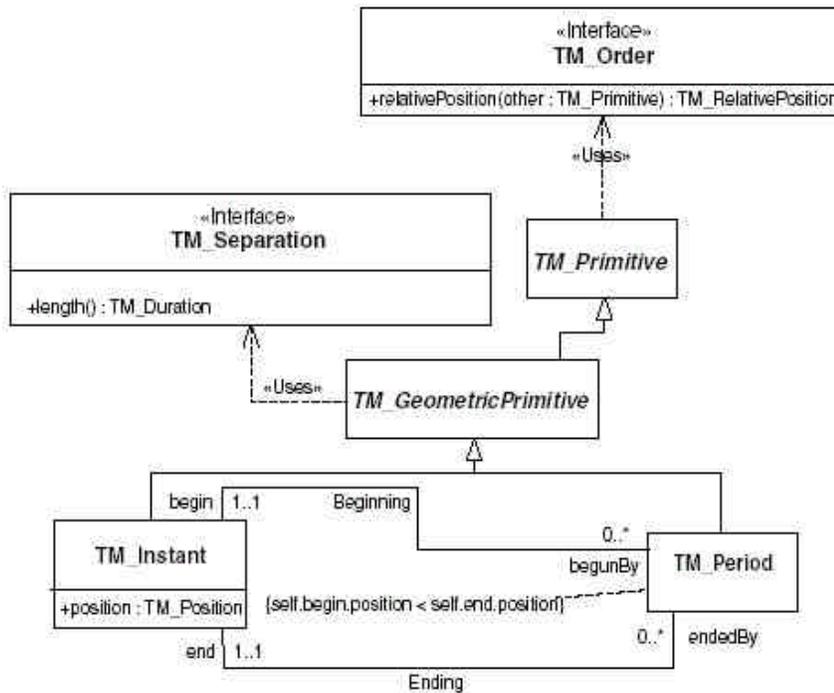

Figure 43 Profile of temporal geometric objects adapted from ISO 19108:2002

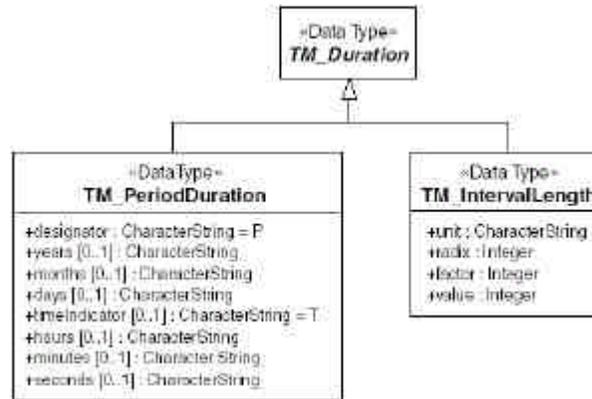

“TM\_Primitive” is represented by the “\_TimePrimitive” object element. Additional properties “relatedTime” representing the result of “relativePosition(other:TM\_Primitive)” operations has been added.

“TM\_GeometricPrimitive” is represented by the “\_TimeGeometricPrimitive” object element. An additional property “\_timeLength” representing the result of the “length()” operation has been added.

“TM\_Instant” is represented by the “TimeInstant” object element. The “position” attribute is represented by the “timePosition” property.

“TM\_Period” is represented by the “TimePeriod” object element. The “begin” and “end” roles are represented by association properties of the same name in GML. These associations have an alternative representation in GML as follows: “end” is in a choice block with “endPosition” and “begin” with “beginPosition”, the latter in each case has simple content as discussed in clause 14.2.3.4.

#### D.2.4.4 Temporal Duration

**Figure 44 DataTypes representing temporal duration ISO 19108:2002**

The GML property element “\_timeLength” is abstract, with either an “timeInterval” or “duration” element substituting. These have XML Schema types which implement the data types shown in Figure 44, as follows:

“TM\_IntervalLength” is implemented using a simpleContent type constructed by adding the XML attributes “unit”, “radix” and “factor” to the XML Schema built-in type “decimal”;

“TM\_PeriodDuration” is implemented by the XML Schema built-in type “duration” (see discussion in clause 14.2.3.7). The XML Schema type “duration” prescribes a literal value with the lexical form described in ISO 8601, which removes the need to implement the list of attributes of the TM\_PeriodDuration class separately.

D.2.4.5 Temporal Position

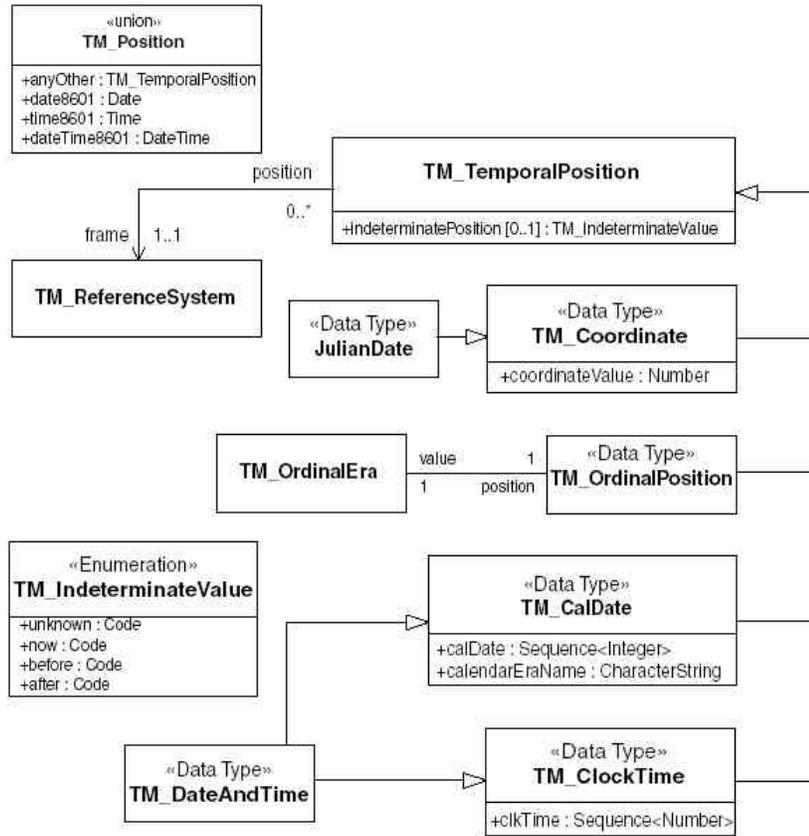

Figure 45 Temporal position, from ISO 19108:2002

Components represented as UML attributes of type TM\_Position are represented as GML properties with XML Schema type gml:TimePositionType. This is a “simpleContent” type the details of whose derivation are described in clause 14.2.3.4. This represents the requirements shown in Figure 45 as follows:

“TM\_Coordinate”, which gives temporal position represented by a single number, is implemented by XML Schema type “decimal”;

“TM\_OrdinalPosition”, which carries an association with a TM\_OrdinalEra, is implemented by XML Schema type “anyURI”, which follows the pattern used in GML where associations are implemented through references;

“TM\_CalDate”, which carries attributes consisting of sequence of numbers for the calendar date, and an era name, is implemented in gml:CalDate by a union (choice) of XML Schema types “date”, “gYear”, “gMonth”, whose lexical representations follow ISO 8601, to which an XML attribute “calendarEraName” is added;

“TM\_ClockTime”, which carries a sequence of numbers describing an instant that recurs daily, is implemented by XML Schema type “time”, whose lexical representation follows ISO 8601;

“TM\_DateAndTime” is implemented by XML Schema type “dateTime”, whose lexical representation follows ISO 8601;

The variants “date8601”, “time8601” and “dateTime8601”, shown in TM\_Position, are implemented by the XML Schema types “date”, “time” and “dateTime”, already introduced;

“IndeterminatePosition” is represented using an XML attribute of the same name;

The role “frame” is implemented using an XML attribute of the same name, whose value has type “anyURI”, which follows the pattern used in GML where associations are implemented through references.

#### D.2.4.6 Temporal Topology

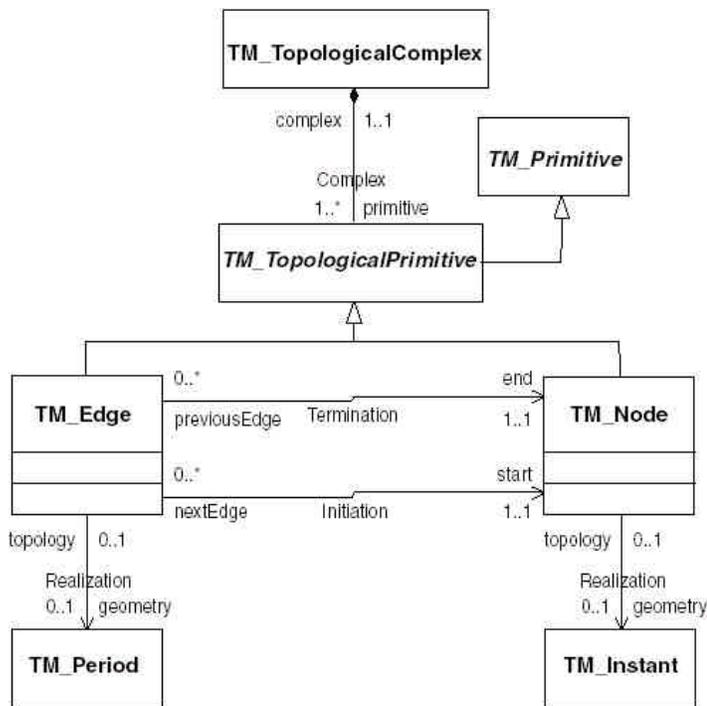

Figure 46 Profile of temporal topology adapted from ISO 19108:2002

“TM\_TopologicalComplex” is represented by the “\_TimeTopologyComplex” object element. The “primitive” role is implemented by a property element of the same name.

“TM\_TopologicalPrimitive” is represented by the “\_TimeTopologyPrimitive” object element. The “complex” role is implemented as a reference by a property element of the same name, though this is made optional.

“TM\_Node” is implemented by the “TimeNode” object element. The “previousEdge” and “nextEdge” roles are implemented by property elements of the same name in GML. The “geometry” role is implemented by the “position” property.

“TM\_Edge” is implemented by the “TimeEdge” object element. The “start” and “end” roles are implemented by property elements of the same name in GML. The “geometry” role is implemented by the “extent” property.

#### D.2.4.7 Temporal Reference Systems

The following UML class diagrams illustrate the profile of the “Temporal Reference Systems” package (compare with figures 7 to 10 of ISO 19108:2002).

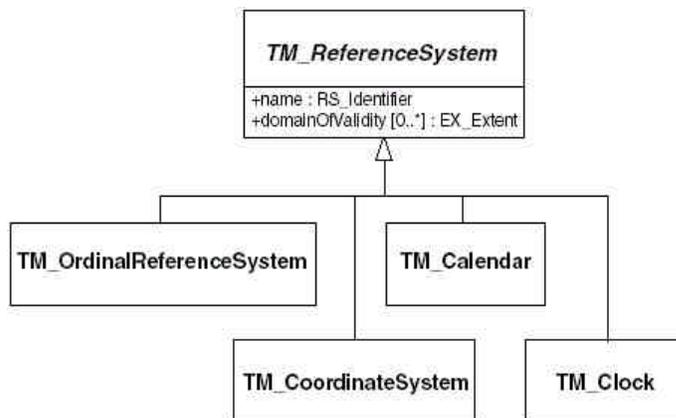

Figure 47 Hierarchy of temporal reference systems from ISO 19108:2002

“TM\_ReferenceSystem” is implemented by the “\_TimeReferenceSystem” object element. The “\_TimeReferenceSystem” element can carry additional properties: an optional “description” element, one or more “name” elements and an optional “gml:id” attribute. The “domainOfValidity” attribute is implemented using an XML attribute of the same name. This has XML Schema type “string” which implements the “description” attribute of EX\_Extent (see ISO 19115:2003).

These properties are inherited by all the components that are substitutable for \_TimeReferenceSystem.

D.2.4.8 Calendars and Clocks

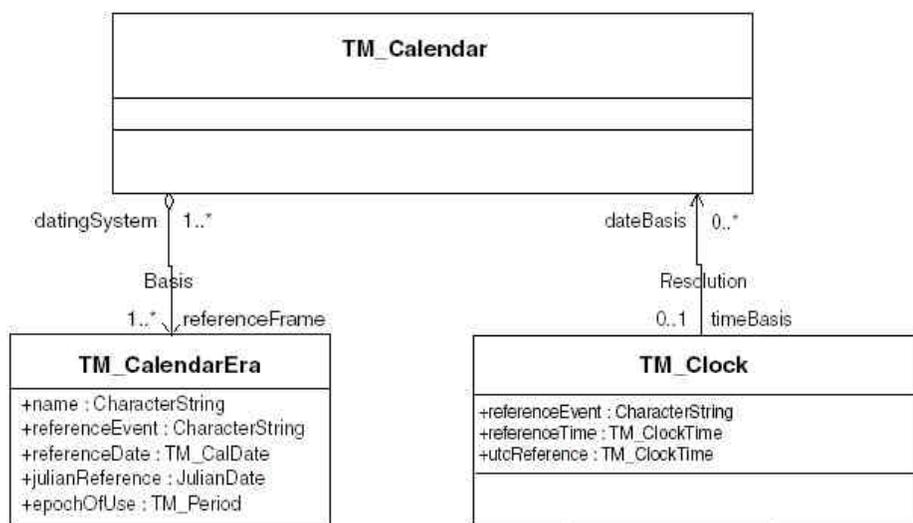

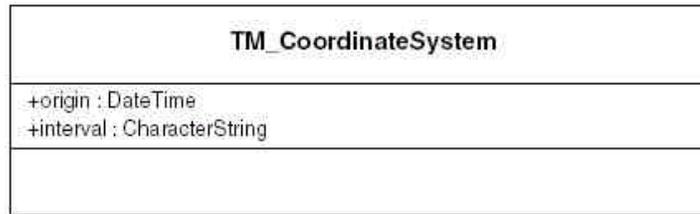

Figure 48 Model for calendar and clock, from ISO 19108:2002

“TM\_Calendar” is implemented by the “TimeCalendar” object element. The “referenceFrame” role is implemented as a property element of the same name.

“TM\_CalendarEra” is implemented by the “TimeCalendarEra” object element. The “referenceEvent”, “referenceDate”, “julianReference” and “epochOfUse” attributes are implemented as property elements of the same names.

“TM\_Clock” is implemented by the “TimeClock” object element. The “referenceEvent”, “referenceTime”, and “utcReference” attributes are implemented as property elements of the same names. The “dateBasis” role is implemented as a property element of the same name.

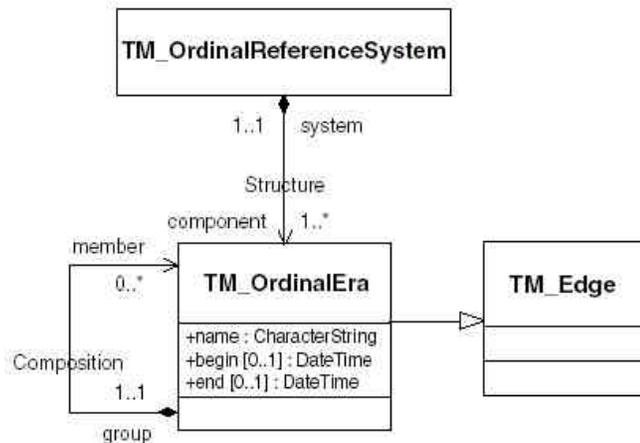

#### D.2.4.9 Time Coordinate Systems

**Figure 49 Model for temporal coordinate system, from ISO 19108:2002**

“TM\_CoordinateSystem” is implemented by the “TimeCoordinateSystem” object element. The “origin” attribute is implemented as a choice of property elements “origin”, which refers to a `TimelInstant`, or “originPosition” which encodes a position directly. The “interval” attribute is implemented as a property element of the same name, using `TimeIntervalLengthType` which follows ISO 11404.

#### D.2.4.10 Temporal Ordinal Reference System

**Figure 50 Model for temporal ordinal reference system, adapted from ISO 19108:2002**

“TM\_OrdinalReferenceSystem” is implemented by the “TimeOrdinalReferenceSystem” object element. The “component” role is implemented as a property element of the same name.

“TM\_OrdinalEra” is implemented by the “TimeOrdinalEra” object element. The “name”, “begin” and “end” attributes are implemented by the “name”, “start” and “end” properties inherited from `TimeEdge`. The “member” role is implemented as property element of the same name. The “group” role is implemented as a reference by a property element of the same name. Optional “description” and “gml:id” properties are also inherited from `TimeEdge`.

#### D.2.4.11 Conformance

The rules governing conformance of a profile with ISO 19108 are described in chapter 2 and annex A of ISO 19108. Concerning the criteria defined in chapter 2, GML as an application schema for data transfer targets conformance with A.1. The conditions of this conformance clause are met by the profile specified above.

### D.2.5 ISO 19109 Rules for App Schema

GML implements a subset of the general feature model defined in ISO DIS 19109.

In addition extensions are implemented by GML. The general feature model is concerned only with feature types whereas an application schema (in GML or UML) will often deal with additional information types. Examples are data types, enumeration types, union types, etc. which all cannot be represented using the general feature model. ISO DIS 19109 therefore specifies that only a one-way mapping from the general feature model to the application schema is possible.

Like in the case of UML, the mapping from the general feature model to the GML feature model described in XML Schema is in general straightforward.

The following changes have been applied to the general feature model of ISO 19109.

**Table 13**

	Change	Explanation
1	GF_FeatureOperation deleted	Operation are not supported
2	Multiplicity of GF_InheritanceRelation/supertype changed to "1"	Only single inheritance is supported and mapped to the type derivation mechanism of XML Schema

Some additional comments on the following metaclasses of the general feature model:

**Table 14**

	Change	Explanation
1	GF_AssociationType	<p>In general, the composition of association roles to associations is not directly represented in GML application schemas.</p> <p>If the relationship between two association roles shall be expressed explicitly in the GML application schema, then the roles may be cross-referenced by</p> <ul style="list-style-type: none"> <li>- representing the element name of the target object class in an applInfo annotation with the source "urn:x-gml:targetObjectType"</li> <li>- representing the property name of the inverse association roles in an applInfo annotation with the source "urn:x-gml:inverseProperty"</li> <li>- optionally representing the name of the association in an applInfo annotation with the source "urn:x-gml:associationName"</li> </ul>
2	GF_Constraint	Constraints may be mapped to schematron constraints or may be just expressed as text in documentation annotations.

The relationship between an application schema in UML and in GML is described as part of the annexes E and F dealing with the mapping between ISO 19109 and GML Application Schemas.

## D.2.6 ISO 19111 Spatial Referencing By Coordinates

ISO DIS 19118 Annex A has been used to map the conceptual model to the corresponding XML Schema definitions. This conversion to XML Schemas was done in a manner that makes the results consistent with GML 3.0. Therefore, the encoding rules used were adapted to produce XML Schemas consistent with the GML 3 schema patterns, and to use some of the predefined XML elements and types defined in the GML 3 schemas.

NOTE See also the proposed changes to ISO DIS 19118 as a result of the encoding rules for GML application schemas specified in Annex E.

Although the conceptual model is to a very large extent based on ISO 19111, it deviates on a number of points and adds a considerable degree of detail, consistent with the need to provide a specification ready for implementation in the geospatial market place. A list of these variations is:

NOTE This list is not completely up-to-date and will need some minor revision. It is the intention that this will result in a proposal for a technical amendment for ISO 19111 (possibly via the WI 19140 process).

- Use of UML

Inheritance of attributes is not dealt with consistently in ISO DIS 19111. In the model used for GML all common attributes and referenced objects have been placed in the highest level (abstract) superclass. This eliminates separate identifiers for SC\_CoordinateReferenceSystem, SC\_CompoundCRS, CC\_Operation and CC\_ConcatenatedOperation.

Conflict with ISO 19111? None. It would not result in any conflict at the implementation level. Only apparent differences exist with the ISO DIS 19111 UML model.

- Coordinate Reference System subtypes

ISO DIS 19111 do not mention subtypes of this class. OGC believes it crucial that this is done, as this subtyping has been part of geodetic practice for many years. The taxonomy is based on the way the effects of earth curvature are dealt with. This has a direct impact on the size of the area for which the coordinate reference system is suited. The main types are:

- geocentric, describing point locations in 3D space; suited to cover the entire earth;
- geographic, describing point locations on or relative to a reference ellipsoid, approximating the geoid over a significant region of the earth;
- projected, treating the earth's geometry as a flat plane, but carefully controlled distortion; typically suited for (parts of) countries;
- engineering, treating the earth's surface as flat, disregarding earth curvature; suited for small areas.

This subtyping has been Implemented by an attribute with enumerated values. This might alternatively be implemented by subclassing, but this would result in a very complex model. A notable addition to the list not mentioned in ISO 19111 is the subtype 'Temporal CRS'.

Conflict with ISO 19111? Yes, although it could be seen as a permitted addition where ISO 19111 describes minimum requirements.

- Coordinate System subtypes

ISO 19111 introduce subtyping at this level, showing however a mixed taxonomy. "Projected" is the outlier here. "Projected" refers to the way earth curvature is dealt with. The ISO taxonomy is, with this exception, by geometry of the coordinate frame. This document honours this subtyping, but adds some types, notably 'linear CS' and 'temporal CS'.

Conflict with ISO 19111? Yes, although it could be seen as a permitted addition where ISO 19111 describes minimum requirements.

- Derived Coordinate Reference Systems

This document adds a concept that is not at all modeled in ISO 19111, viz. 'Derived CRS'. Some CRSs cannot exist without the relationship with a source CRS having been defined, as is the case with a projected CRS. This requires the following changes to the ISO 19111 model:

- a self-reference relationship in SC\_CoordinateReferenceSystem, permitting a source CRS to be defined for a derived CRS;
- a relationship between SC\_CoordinateReferenceSystem and CC\_Conversion, permitting the defining coordinate conversion to be specified.

Making the two relationships from CC\_CoordinateOperation to SC\_CRS optional, to permit the source and target CRS to not be specified in the case of a Defining Conversion. Leaving these relationships mandatory would lead to a potential data conflict, as the information about source and target CRS would be duplicated.

The ISO 19111 URL schema of figure B.1 in ISO 19111 documents a relationship between SC\_CoordinateSystem and SC\_Ellipsoid that is not described in the text. Since the same diagram shows a relationship to CC\_Operation, equally not found back in the text, it is assumed that this is an (unsatisfactory) attempt to model projected CRSs. It is unsatisfactory because the document gives no indication how this is to be done. Furthermore, any literal implementation would result in a number of practical problems. It is for these reasons that the constructs in this document are proposed as an alternative, improved way to achieve inferred objective.

Conflict with ISO 19111? Yes.

- Coordinate operations

Modelling detail has been added in the area of coordinate operations. A new superclass CC\_CoordinateOperation has been created to capture the shared attributes and relationships of the CC\_Operation and CC\_ConcatenatedOperation classes. In addition three more new classes have been created:

- CC\_OperationMethod
- CC\_OperationParameter
- CC\_ParameterValue

One of the two reasons was normalisation, to avoid repetition of attribute values in instantiated objects.

The more important reason was to create a structure that permits being prescriptive about what operation parameters are used by what method. It permits being prescriptive about the operation methods themselves. This part of the model comes close to the heart of coordinate transformation software. The prevalence of distributed computing necessitates standardisation in the data: a coordinate operation may be requested specifying an operation method that is not recognised by the server software. If it does recognise the method, it may not recognise the operation parameters quoted. Is the parameter called 'scale factor at central meridian', 'scale factor at natural origin', 'false magnification', etc? The modelling construct proposed is derived from the EPSG data model, that has proven to be able to resolve this issue.

Conflict with ISO 19111? Yes, but it is quite possible to interpret the extra classes as additional detail implementing the more general ISO 19111 model.

Additionally, some of the changes have been introduced to slightly better support conversion to XML Schemas.

Wherever a GML object is associated with a Coordinate Reference System, this is implemented by an attribute ("srsName") pointing to a gml:CoordinateReferenceSystem element.

## D.2.7 ISO 19112 Spatial Referencing By Geographic Identifiers

GML does not provide a pre-defined schema for gazetteers. However, it does provide pre-defined properties for spatial references by geographic identifiers:

- The property <gml:LocationString> contains or references a text that describes the location.
- The property <gml:LocationKeyword> is a code usually selected from a controlled list, e.g. a ZIP code.

### **D.2.8 ISO 19115 Metadata**

GML does not provide an information model for metadata. Instead a mechanism to include or reference metadata is provided for all object elements.

**NOTE** As specified in clause 7.5.8, if metadata following the conceptual model of ISO 19115:2003 shall be encoded in a GML document, the corresponding Implementation Specification specified in ISO WD 19139 shall be used to encode the metadata information.

### **D.2.9 ISO 19117 Portrayal**

#### **D.2.9.1 Overview**

This section provides a comparison of ISO 19117 and the GML Default Style Specification from GML. Since GML Default Style was not directly derived from ISO 19117 some additional background explanation is required.

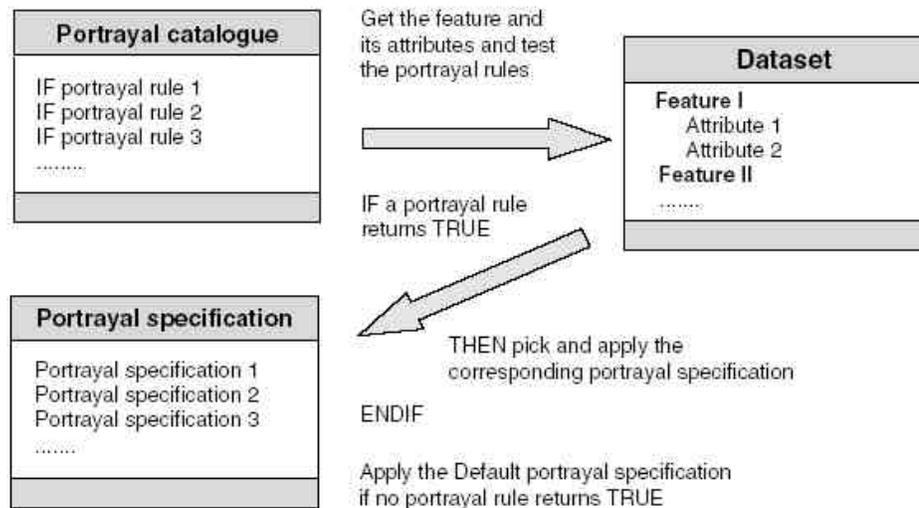

GML Default Style is intended as an implementation specification that provides an XML mechanism for the description of rules for the styling of GML into SVG. It makes use of XML, XML Schema, XLink, XPath (2.0) and SVG. Note that SVG is capable of displaying both vector and image graphics including in particular tiff, png and jpeg image formats.

GML Default Style does not break the principle of separating content and presentation. It does provide a mechanism by which application schema developers can associate graphical presentation styles, expressed in SVG, with GML features. These are to be treated as default styles and may be ignored by a styling application.

This section compares the principles, conformance clauses and specific mechanisms of ISO 19117 with those of this version of GML.

#### **D.2.9.2 Portrayal Mechanism from ISO 19117**

The basic portrayal mechanism from ISO 19117 is illustrated in Figure 51 (this is Figure 2 in ISO/DIS 19117):

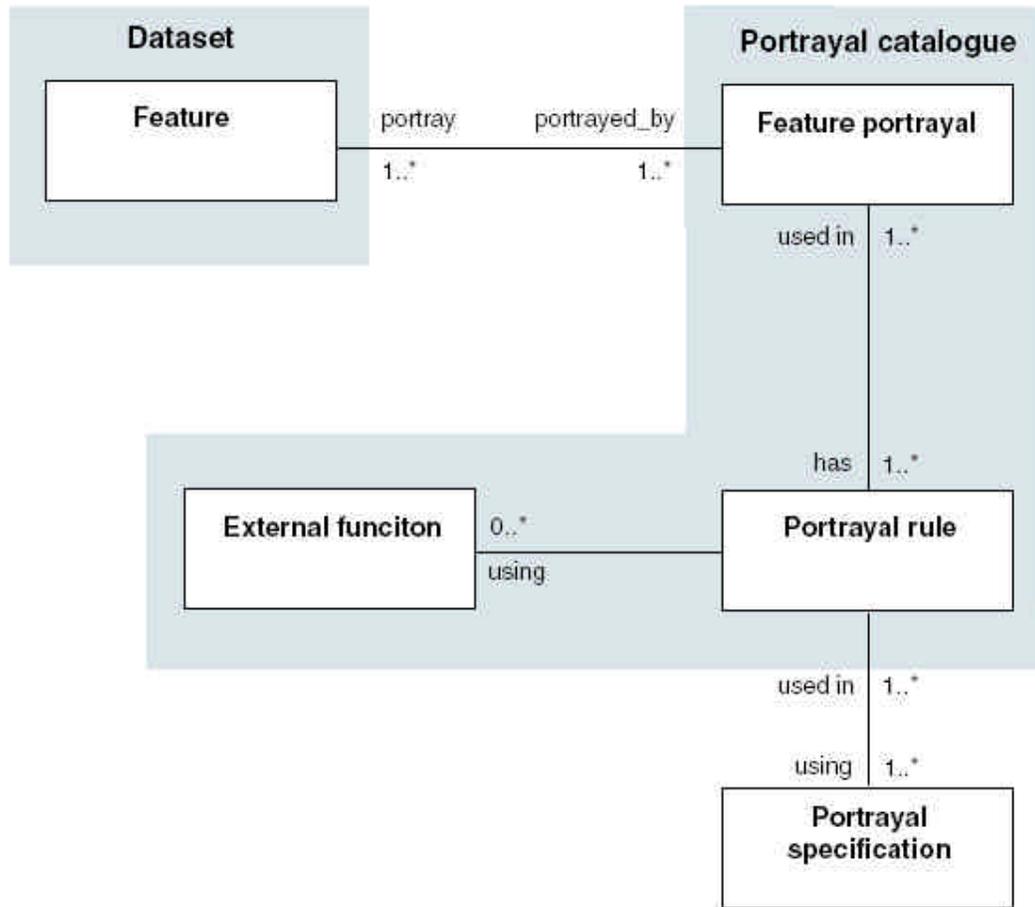

**Figure 51 – ISO 19117 Portrayal Mechanism**

The following basic principles of ISO Portrayal are summarized in the figure:

- a) It is based on a declarative rule structure (e.g. If (portrayal rule) then Apply (portrayal specification) else (apply default portrayal specification).
- b) Datasets and Portrayal Rules are separate from one another or must be capable of being separated from one another.
- c) Portrayal rules can be organized into catalogues.
- d) Portrayal rules select what is to be portrayed in the dataset.
- e) Portrayal specifications state how what is selected in the portrayal rule is to be graphically presented.

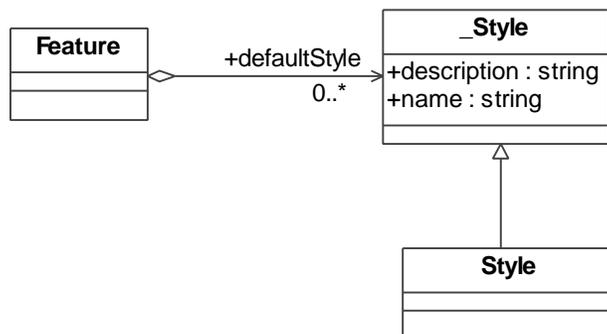

Figure 51 is reinforced by the high level UML model in ISO 19117 shown here as Figure 52.

**Figure 52 – Portrayal UML Diagram from ISO 19117**

Note that Features are associated with 1 or more FeaturePortrayals with the role of the FeaturePortrayal as portrayed\_by.

In GML Default Style the property <gml:defaultStyle> is introduced. This property has the schema as shown in Figure 53 and is equivalent to ISO 19117 portrayed\_by association role.

**Figure 53 – gml:defaultStyle property associates feature instance and style**

The GML defaultStyle property can encapsulate a style definition or can reference one using the xlink:href property. This then corresponds to the UML diagram.

```
EXAMPLE    <abc:Road gml:id="r1">
            <gml:defaultStyle xlink:href ="http://www.mysite.org/mystyle.xml" />
            <abc:numLanes>3</abc:numLanes>
        </abc:Road>
```

Styles in GML default style can be referenced as shown or can appear in-line i.e. inside the gml:defaultStyle property.

GML defaultStyle provides a concrete Style element for which the styling grammar is specified and an abstract substitution group head gml:\_Style to which one can equivalence some other concrete style element with a different styling grammar.

Styles thus correspond to Portrayal Catalogues in ISO 19117. FeaturePortrayal objects consist of the gml:FeatureStyle element together with the featureType attribute.

The Feature Portrayal (ISO 19117) has one or more Portrayal Rules. A Portrayal Rule is in effect a filter to select a feature instance based on its attributes or associations to other features.

EXAMPLE An example from ISO 19117 document is:

```
(Road.classification .EQ. "country road")
```

In GML Default Style the Portrayal Rule is handled by one of the style elements, namely:

- FeatureStyle (cardinality 0 to unbounded)
- Graph Style

FeatureStyle is intended to describe the portrayal rules and portrayal specification (ISO terminology) for a Feature, and can be correlated to the ISO 19117 PF\_FeaturePortrayal class.

Graph Style has no correlate in ISO 19117 and refers to the portrayal of 1-D graphs from feature collections.

The FeatureStyle element references the associated feature-type using the featureType attribute as in: (this is part of FeaturePortrayal in ISO 19117).

```
<gml:FeatureStyle featureType = "Road"> ... </gml:FeatureStyle>
```

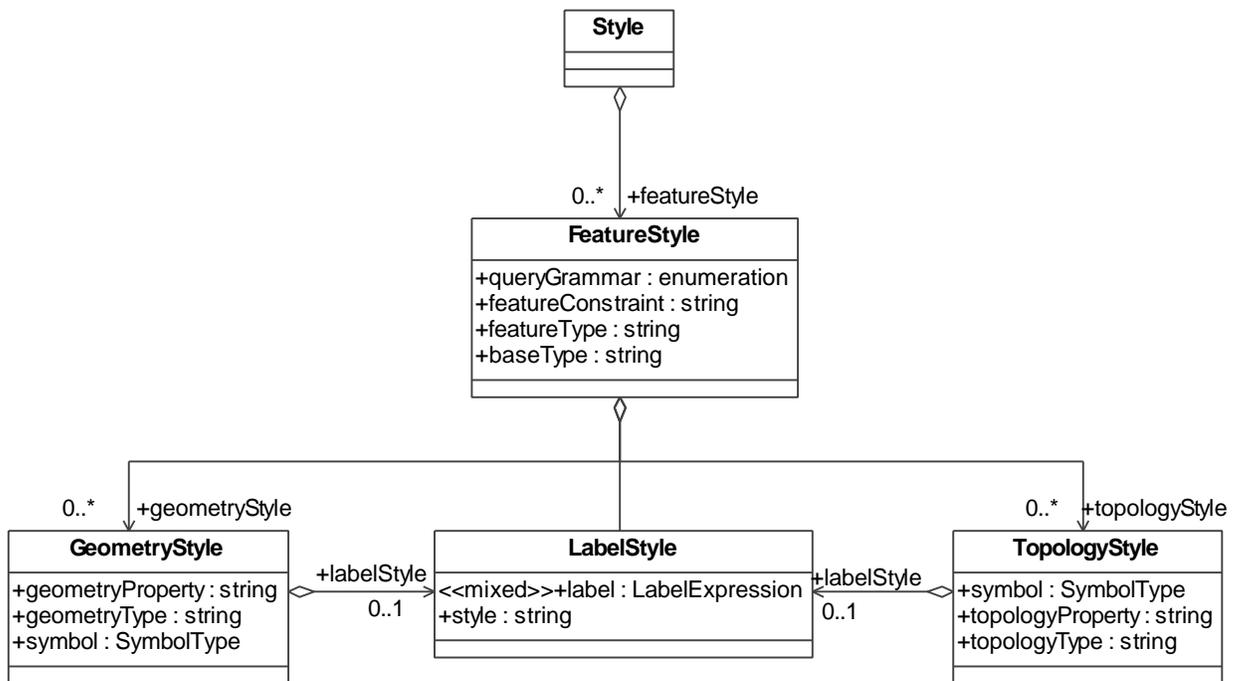

The Portrayal Rule (ISO 19117) is then constructed using the gml:FeatureStyle in conjunction with the featureConstraint. featureConstraint is an XPath expression that is applied against all features of type = feature-type.

```
EXAMPLE    text(abc:Road/abc:classification) = "country road"
```

This selects all abc:Road features with classification property of "country road".

The featureConstraint corresponds to the ISO 19117 feature PortrayalRule. The results of applying the XPath expression to a feature of type = feature-type is then styled in accordance with contents of the Feature Style which can include references to external presentation information.

NOTE GML allows only a single featureConstraint per each FeatureStyle, but that there can be any number of FeatureStyle elements in a Style.

**Figure 54 – Feature Style UML Model**

### D.2.9.3 Portrayal Service

The Portrayal Service is a service to portray feature instances. It has one method in the ISO UML model, namely `portrayFeature`. Since GML Default Style is only concerned with the implementation of style description such an abstract Portrayal Service is not required in the GML default style specification. The operation `portrayFeature` takes the arguments: a list of feature instances and a `portrayalCatalogue` consisting of one or more portrayal rules.

### D.2.9.4 Portrayal Catalogue

This package defines the classes:

- `PF_PortrayalCatalogue`
- `PF_FeaturePortrayal`
- `PF_PortrayalRule`
- `PF_ExternalFunction`
- `PF_AttributeDefinition`

The contents of the package are shown in Figure 55. Note that a `PF_PortrayalCatalogue` is an aggregation of one or more `PF_FeaturePortrayal` classes each containing 1 or more `PF_PortrayalRule` classes.

Portrayal rules may invoke external functions. Signatures of such external functions are described using `PF_ExternalFunction`. Formal parameters associated with these external functions are provided by the `PF_AttributeDefinition` class.

The Portrayal Specification is associated with one or more Portrayal Rules.

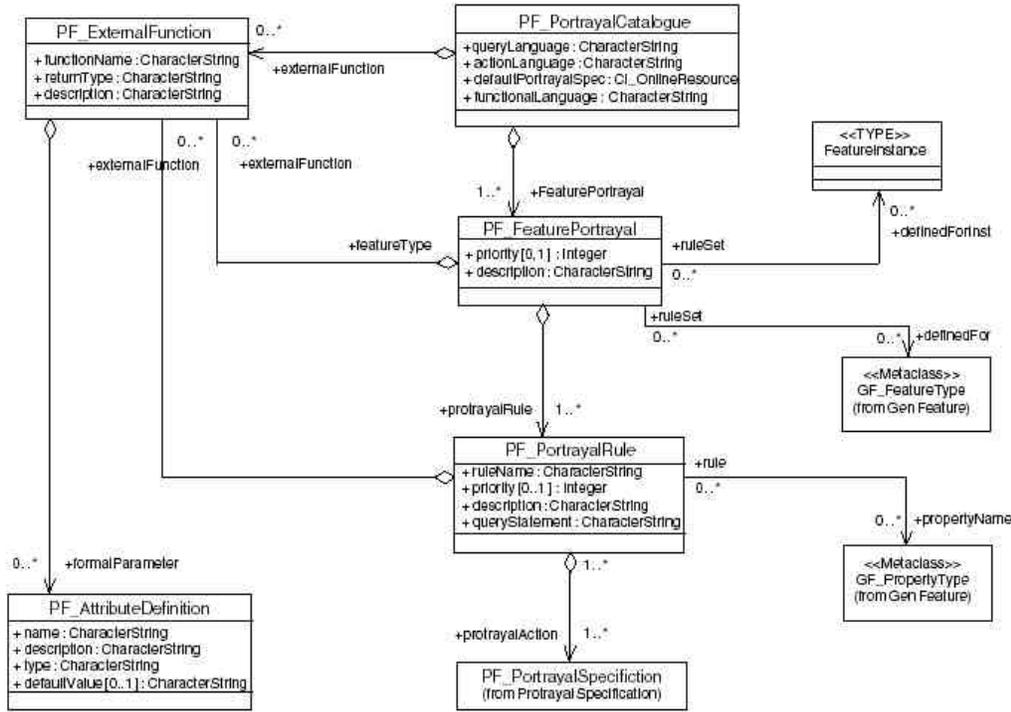

Figure 55 – Portrayal Catalogue UML Model

**D.2.9.5 PF\_PortrayalCatalogue**

This class is an organization of a set of feature portrayal rules. It corresponds to a gml:Style in GML default style.

The attributes of PF\_Portrayal Catalogue are:

- queryLanguage – this specifies notation for how queries are defined.
- actionLanguage – this specifies the notion for how actions are performed.
- defaultPortrayalSpec
- functionalLanguage – name of the functional language used.

In the abstract specification of ISO 19117 queryLanguage is OCL and the actionLanguage is UML.

In GML Default style the queryLanguage is XPath, the actionLanguage is XPath/SVG/CSS2 and the functionalLanguage is XPath.

The associations of PF\_PortrayalCatalogue are:

- featurePortrayal – a list of featurePortrayal objects
- externalFunction – references a list of external functions

In GML default style the gml:Style is equivalent to a PF\_PortrayalCatalogue.

A `gml:Style` contains one or more `FeatureStyle` elements via `featureStyle` associations. These contain the portrayal rules that are applied to the GML instances.

#### **D.2.9.6 PF\_FeaturePortrayal**

The `PF_FeaturePortrayal` refers to a feature class through the `feature name` attribute. There is the `definedFor` feature association that refers to the feature type.

NOTE This is what the text says, but not what the UML shows!

In GML default style we have the `featureType` attribute of the `FeatureStyle`. This corresponds to the `PF_FeaturePortrayal` object.

`PF_FeaturePortrayal` has an optional attribute `Priority`. This is not supported in GML default style.

`PF_FeaturePortrayal` has a `description` attribute. In GML default style we have the equivalent `description` attribute on `FeatureStyle` type inherited from the base GML object (`_GML`)

#### **D.2.9.7 PF\_PortrayalRule**

`PF_PortrayalRule` is a portrayal rule and corresponds in GML to the `featureConstraint` element of `FeatureStyle`. In GML, the content of this element is an XPath/XQuery expression that is assumed to have access to all properties of features referenced by the containing `FeatureStyle` element.

`PF_PortrayalRule` has the following attributes:

- `ruleName` = name of the rule – `gml:name` property of `gml:FeatureStyle` element.
- `priority` = priority between rules – NOT supported in GML.
- `description` = description of the rule – `gml:description` property of `gml:FeatureStyle` element.
- `queryStatement` – a formal specification in the stated query language that evaluates to True or False. In GML this is the `featureConstraint` property. This can be viewed as being applied to the GML instances and evaluating to an XPath node set containing the feature instances that satisfy the constraint OR being used in the `match` attribute of an XSLT template that when true invokes the action part of the template. The interpretation is thus implementation dependent.

`PF_PortrayalRule` has the associations:

- (list of) external functions – this is done in GML via the XSLT extension function mechanism.
- `portrayalAction` – formal expression in the action language including pre-processing statements and calls to portrayal operations. This is done in GML through XPath and implicit calls to SVG operations.

#### **D.2.9.8 Portrayal Specification**

The Portrayal Specification package defines the following classes:

- `PF_PortrayalSpecification`
- `PF_PortrayalOperation`
- `PF_ParameterSet`
- `PF_AttributeValue`

- PF\_AttributeDefinition (Defined in Portrayal Catalogue Package)

#### D.2.9.9 PF\_PortrayalSpecification

This holds instances of the portrayal specification, one for each PF\_PortrayalOperation. The symbol association role points to each related PF\_PortrayalOperation.

The equivalent entity in GML default style is gml:GeometryStyle class. It contains all the styling specification for the geometry of the features selected by the featureConstraint filter. GML also defines the gml:LabelStyle class which is responsible for specifying the styling information for the text output. The gml:LabelStyle can be used as the value of the gml:labelStyle property within gml:GeometryStyle element.

gml:GeometryStyle class has the gml:symbol property whose value is an SVG fragment. This value can be referenced remotely or specified inline in the gml:symbol property. The value of the symbol specifies all the operations that need to be performed in order to draw the feature in a desired way.

#### D.2.9.10 PF\_PortrayalOperation

PF\_PortrayalOperation holds the name and description of portrayal operation.

In GML all portrayal operations are SVG drawing operations. SVG does not provide explicit methods, but rather specifies the geometric object and its parameters with the operation part being implicit.

EXAMPLE If we write in SVG

```
<path style="stroke-width:2;fill:none;stroke:brown;" id="" d="M186,479L187,480L190,479L188,477"
onclick="featureClicked('exp:FillEmbankment:', ")/>
```

then we can read this as if we have a method drawPath with the above parameters.

Thus, PF\_PortrayalOperation and classes associated with it through formalParameter and parameterSet associations are all defined implicitly in the SVG.

Explicit function calls in GML Default Style (to map the GML geometry into the SVG geometry) can be done however through an XPath expression that generates the SVG. Note that the ISO 19117 Portrayal Specification does not provide any visibility into the mapping between the geographic objects geometry and the geometry of the graphic portrayal.

#### D.2.9.11 Portrayal of textual data

In GML Default Style, textual data is portrayed using gml:LabelStyle element. This element can be used in the FeatureStyle element in order to portray one label for the whole feature. It can also be, at the same time, specified inside the gml:GeometryStyle (or gml:TopologyStyle) element to provide a label for different geometry (or topology) aspect of the feature.

While in ISO 19117 textual data can be handled in two ways: as an attribute of a feature or by annotation schema, the latter option is not available in the GML default style.

#### D.2.9.12 Representation of symbols

GML default style uses symbols via gml:symbol property of the gml:GeometryStyle element. The property can reference a remote symbol or contain it inline as the value. If referenced remotely, the constraint on reference expression is that it be a valid URI. While it is assumed that the symbols will be managed using symbol libraries and symbol identifiers, it is not a requirement. Any valid URI that evaluates to a symbol can be used.

### D.2.9.13 Tabular Comparison

The UML model of the GML profile defined in this annex describes a conceptual model of the abstract types defined in ISO 19117. The Table 15 maps GML default style class and property names to the corresponding class names and their attributes in ISO 19117 to simplify comparison with that standard.

**Table 15**

<b>GML construct</b>	<b>ISO 19117 construct</b>
gml:_Style (Abstract Class)	Not supported
gml:defaultStyle (property)	portrayed_by (Role)
gml:Style (Class)	PF_PortrayalCatalogue (Class)
gml:featureStyle (property)	featurePortrayal (Association)
gml:FeatureStyle (Class)	PF_FeaturePortrayal (Class)
gml:featureType (attribute)	definedFor (Association)
gml:graphStyle (property)	Not supported.
gml:GraphStyle (Class)	Not supported.
gml:featureConstraint (property)	portrayalRule (Association)
gml:geometryStyle (property)	portrayalAction (Association)
gml:GeometryStyle (Class)	PF_PortrayalSpecification (Class)
gml:topologyStyle (property)	Not Supported
gml:TopologyStyle (Class)	Not Supported
gml:labelStyle (property)	portrayalAction (Association)
gml:LabelStyle (Class)	PF_PortrayalSpecification (Class)
gml:spatialResolution (property)	Not specified
gml:symbol (property)	parameterSet (Association)
SVG Object (the value of gml:symbol property)	PF_ParameterSet (Class)
gml:styleVariation (property)	Handled within PF_ParameterSet (Class)
smil20:animate (property)	Not supported
smil20:animateMotion (property)	Not supported
smil20:animateColor (property)	Not supported
smil20:set (property)	Not supported

### D.2.9.14 Conformance

The following table presents the conformance of the GML Default Styling according to the clauses from the Abstract Test Suite of the ISO Portrayal specification. The clauses were taken from the ISO 19117:2003(E) document.

ISO Abstract Test Suite Clause	GML Conformance
<p><b>A.1 Portrayal schema</b></p> <p>a) Test purpose: To verify conformance to the portrayal schema.</p> <p>b) Test method: Verify that the portrayal specifications and portrayal rules are not part of the dataset to be portrayed, and that the portrayal specifications are stored separately and referenced from the portrayal rules. The portrayal specifications may be stored externally and referenced using a universal reference standard like URL. Verify that the portrayal rules are stored in a portrayal catalogue, and that the portrayal rules are specified for the feature classes they will be applied on. Verify that the portrayal rules are expressed using UML.</p>	<p><b>YES.</b></p> <p>Portrayal rules are not expressed using UML, except in the document specification of those rules (e.g. XQuery).</p>
<p><b>A.2 Availability of portrayal information</b></p> <p>a) Test purpose: Verify that portrayal information is present.</p> <p>b) Test method: Verify that portrayal catalogue and portrayal specification are present, or referenced from appropriate metadata.</p>	<p><b>YES</b></p>
<p><b>A.3 Priority attribute</b></p> <p>a) Test purpose: To verify correct use of priority attributes.</p> <p>b) Test method: Verify that all the portrayal rules have a priority attribute if priority attributes are used. Verify that if two portrayal rules returning TRUE have the same priority value, then the application shall decide which one takes precedence.</p>	<p><b>Not Applicable</b></p> <p>(Priority attribute not used)</p>
<p><b>A.4 Default portrayal specification</b></p> <p>a) Test purpose: To verify that a default portrayal specification is present.</p> <p>b) Test method: Verify that a default portrayal specification is associated with the dataset.</p>	<p><b>YES</b></p> <p>In GML the style associated with the data set via the <code>gml:defaultStyle</code> property is the default style.</p>
<p><b>A.5 External function</b></p> <p>a) Test purpose: To verify correct use of external functions.</p> <p>b) Test method: Verify that the portrayal catalogue lists the external functions used, including the parameters and returned values.</p>	<p><b>YES.</b></p> <p>Drawing functions are implicit in the SVG grammar.</p> <p>Other external functions may be obtained from the engine that processes the query language (XQuery), but in general is implementation dependant.</p>

## D.2.10 ISO 19123 Coverages

The UML model of the GML profile defined in this annex describes a conceptual model of the abstract types defined in ISO DIS 19123. Table 16 maps GML Coverage object and property names to the corresponding class names and their attributes in ISO 19123 to ease the comparison with that standard.

**Table 16**

<b>GML construct</b>	<b>ISO 19123 construct</b>
_Coverage (AbstractCoverageType)	CV_Coverage
boundedBy (property)	domainExtent (attribute)
domainSet (property)	domainElement (role name)
rangeSet (property)	rangeElement (role name)
ValueArray, or _ScalarValueList	AttributeValues
coverageFunction (property)	CV_CoverageFunction (Association)
GridFunction	CV_GridValuesMatrix
sequenceRule (property)	sequencingRule (attribute)
SequenceRuleType	CV_SequenceRule
SequenceRuleNames	CV_SequenceType
incrementOrder (attribute)	scanDirection (attribute)
startPoint (property)	startSequence (attribute)
Grid	CV_Grid
GridEnvelope	CV_GridEnvelope
Low (property)	low (attribute)
high (property)	high (attribute)
RectifiedGrid	CV_RectifiedGrid or CV_RectifiableGrid
origin (property)	origin (attribute)
(set of) offsetVector(s) (property)	offsetVectors (attribute)
MultiPointCoverage	CV_DiscretePointCoverage
MultiCurveCoverage	CV_DiscreteCurveCoverage
MultiSurfaceCoverage	CV_DiscreteSurfaceCoverage
GridCoverage or RectifiedGridCoverage	CV_DiscreteGridPointCoverage

The following additional changes have been applied to the coverage package of ISO 19123.

Table 17

Change	Rationale
All subclasses of CV_ContinuousCoverage deleted.	Currently not supported by GML
Coordinate Reference System association deleted from CV_Coverage	Replaced by srsName (or frame) attributes on the Geometry or Temporal objects in the domain. The GML coverage package allows for domain objects to be in different coordinate reference systems (or reference frames)
CV_CommonPointRule deleted	Currently not supported by GML
AttributeValues deleted	Replaced by a choice between the GML analogues: ValueArray or _ScalarValueList
CV_GeometrValuePair deleted	Replaced by a choice block consisting of a choice between MappingRule or GridFunction
CV_GridValuesMatrix deleted	The mapping between grid points and range values including sequence rule, etc. is contained in an object (GridFunction) that does not inherit from Grid.
CV_GridCell	Currently not supported by GML

The UML class diagram in Figure 56 illustrates the profile of the “Coverage root” package (compare with Figure 2 of ISO 19123).

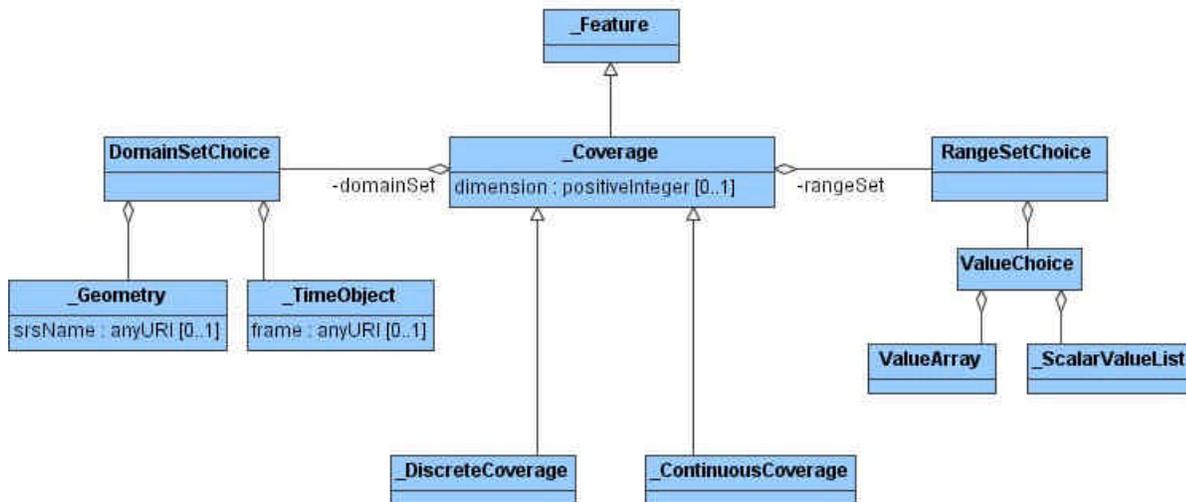

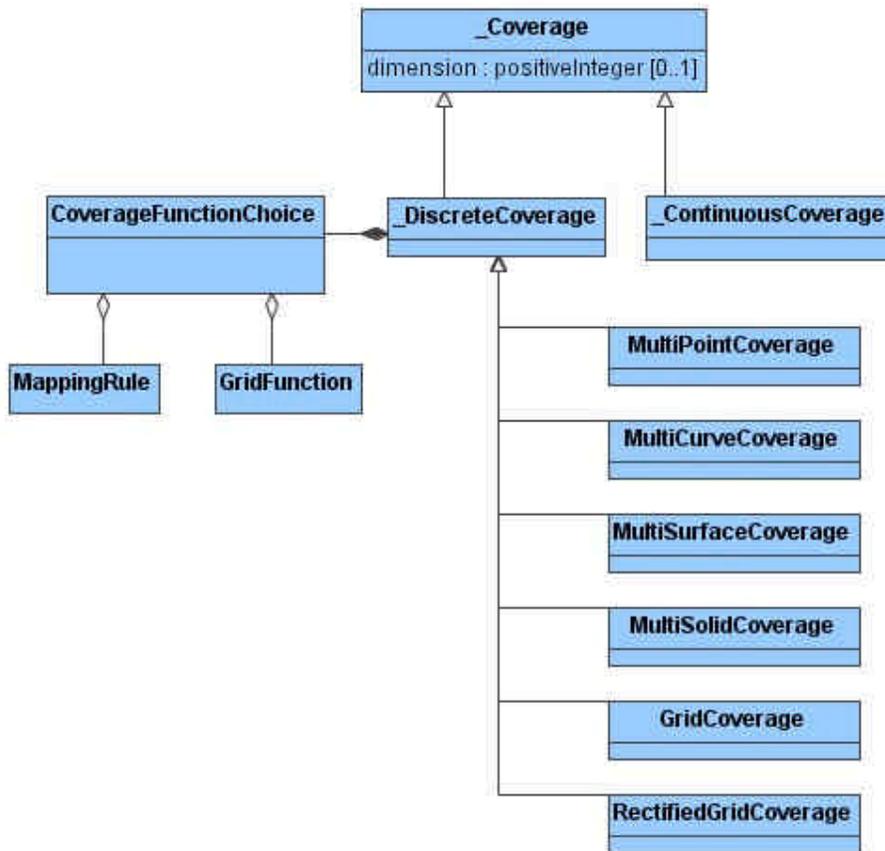

Figure 56

The UML class diagram in Figure 57 illustrates the discrete coverages (compare with Figures 3, 4 and 5 of ISO 19123).

**Figure 57**

The rules governing conformance of a profile of ISO 19123 are described in chapter 2 and annex A of ISO DIS 19123.

The conditions of the following conformance clauses are met:

- a. A.1 Simple coverage interface
- b. A.2 Discrete coverage interface

Note that derived attributes are treated as operations and it is assumed that the derived attributes will be derived from the data by the application handling the GML instances.

## **D.3 Extension of the profile of the ISO 19100 Harmonized Model used by GML**

### **D.3.1 Overview**

This section defines the additional parts of GML that are not covered by the profile defined in the previous section. UML is used as the conceptual schema language to describe the additional elements in accordance with ISO PDTS 19103. For details on the semantics of the additional classes see chapters 7 to 20.

For every XML Schema document that is part of the GML namespace a package of the same name (without the ".xsd" extension) is defined. The required additional classes are defined in each package. The packages are part of a package "GML".

### D.3.2 Package "basicTypes"

In addition to those types from ISO PDTS 19103, the schema basicTypes.xsd defines a number of additional types that are used by other GML schemas.

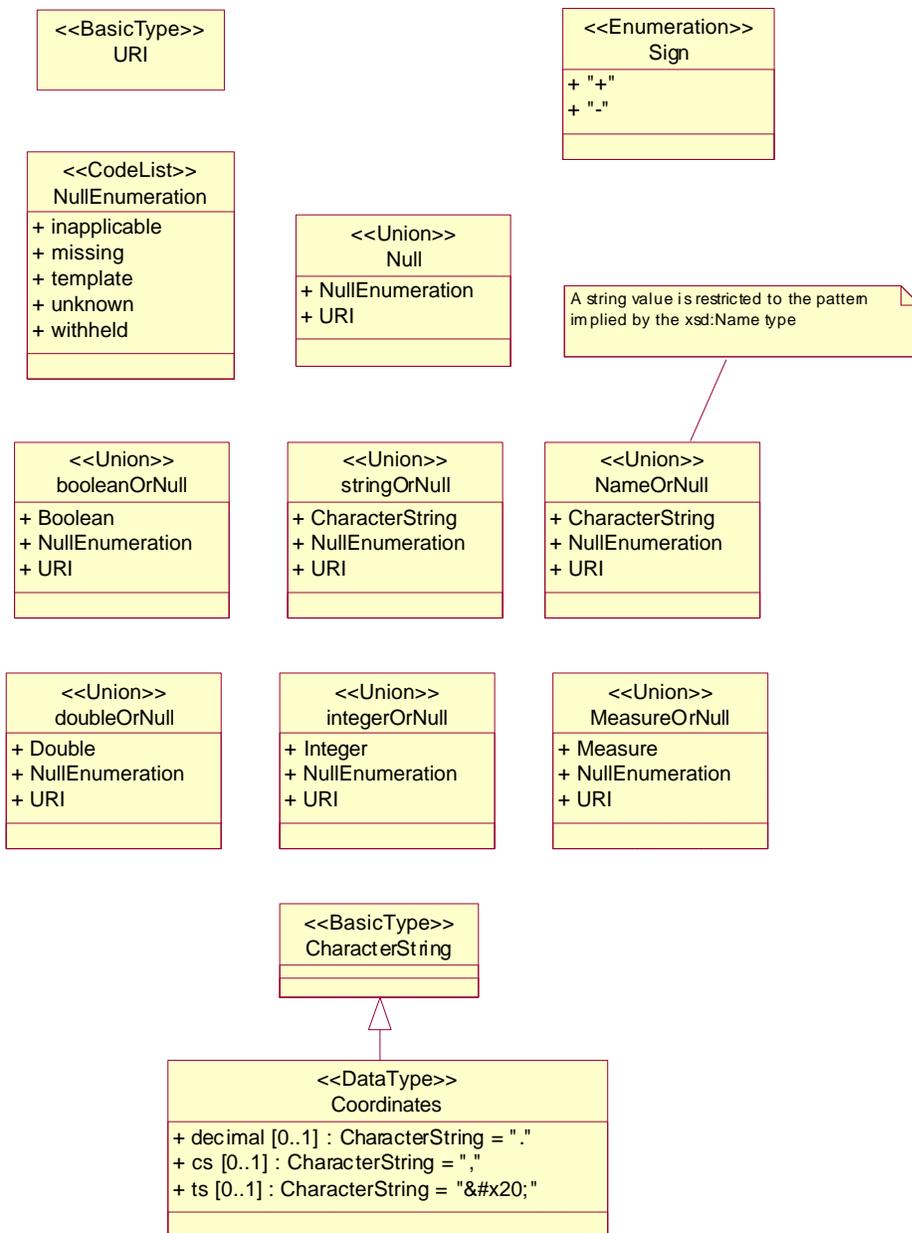

Figure 58

### D.3.3 Package “gmlBase”

The GML Schema gmlBase.xsd does not define additional concepts besides those that are part of the mapping from the conceptual schema to the XML Schema implementation (e.g. representation of object types, associations, etc.; see annex E for more details).

### D.3.4 Package “dictionary”

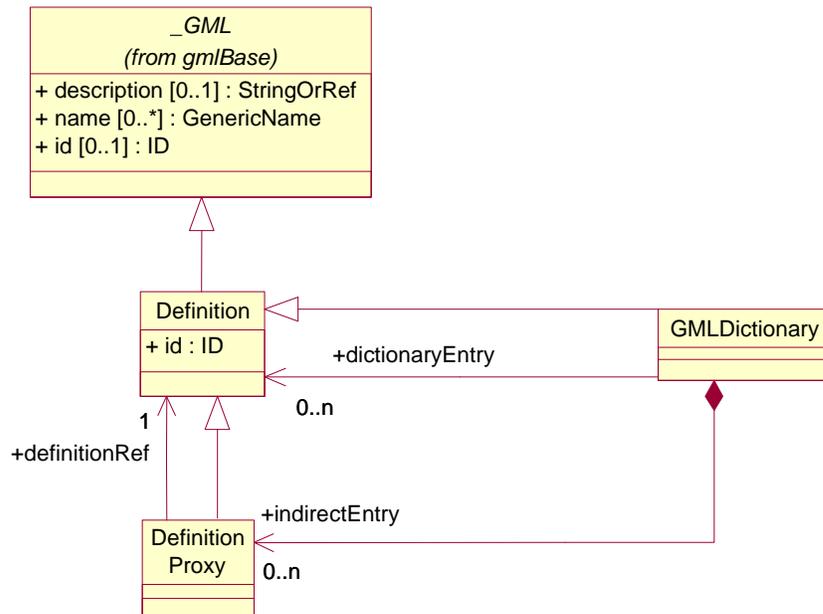

Figure 59

NOTE The “Dictionary” class had to be named GMLDictionary to avoid a naming conflict with the class with the same name in ISO 19103.

D.3.5 Package “units”

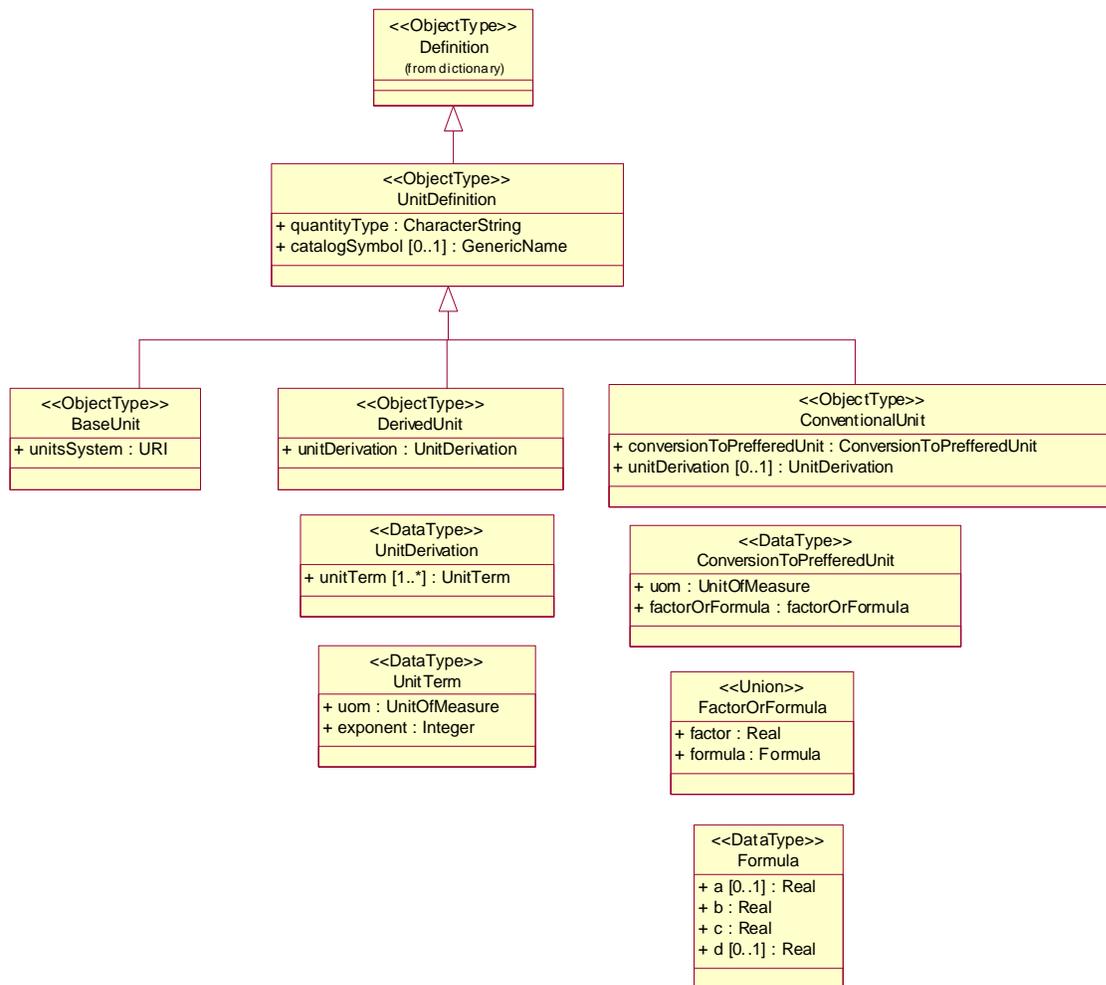

Figure 60

D.3.6 Package “measures”

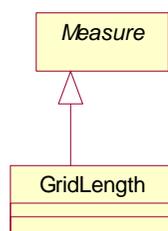

Figure 61

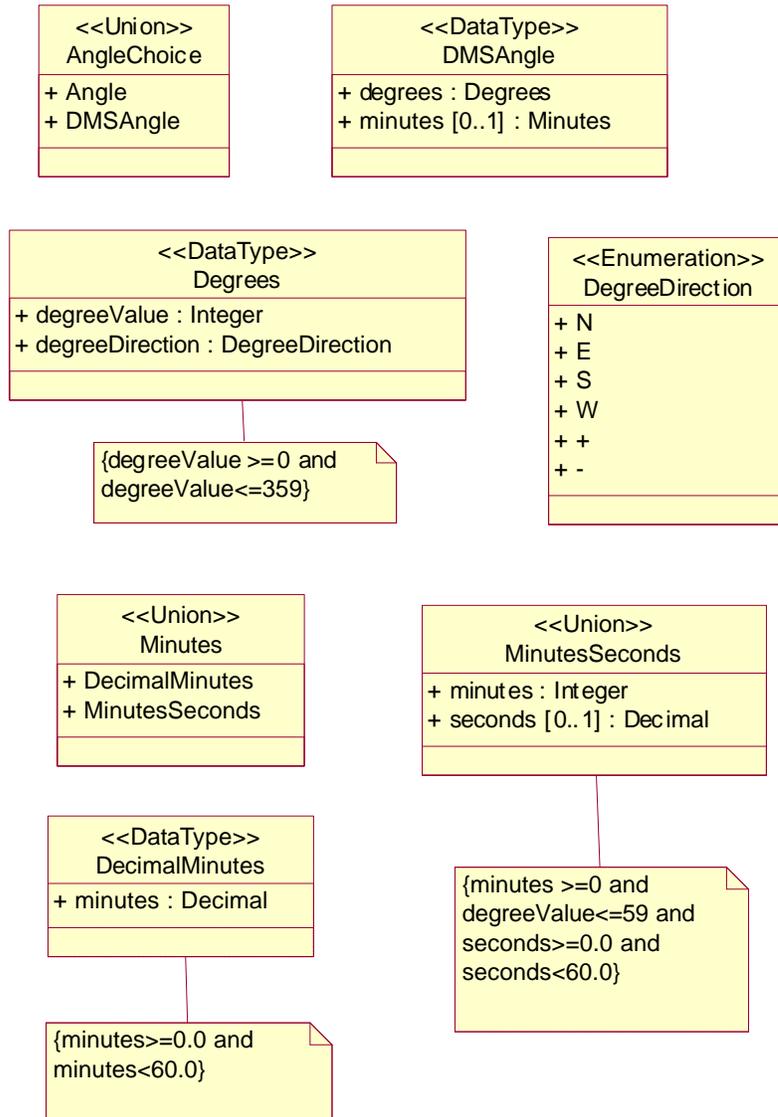

Figure 62

D.3.7 Package “geometryBasic0d01”

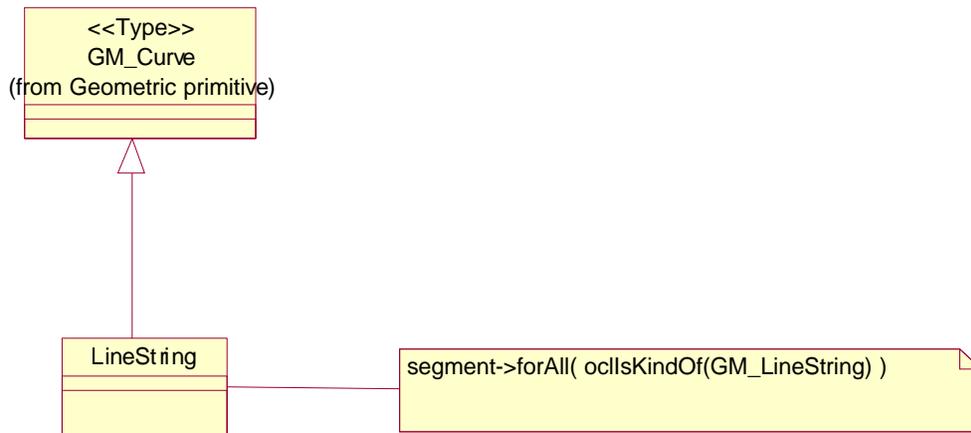

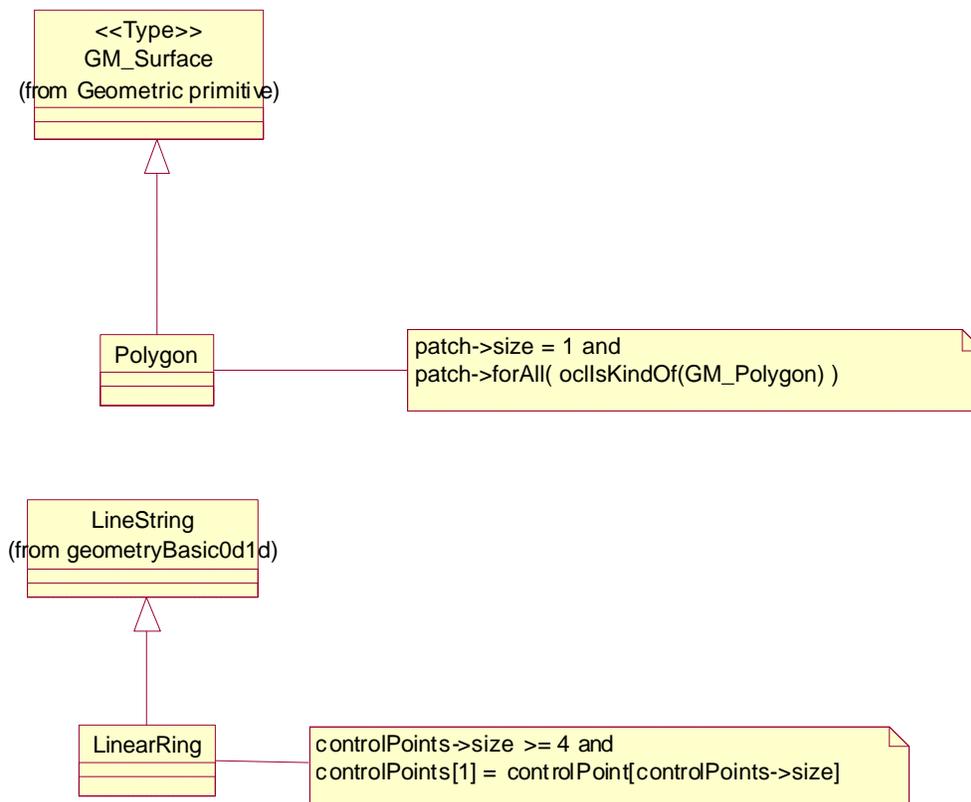

Figure 63

An additional subtype of GM\_Curve is added in GML. “LineString” is a special curve that consists of only GM\_LineString segments. The XML representation of the “LineString” object element joins all the segments into one segment and its control points are represented as direct properties of the “LineString”.

D.3.8 Package “geometryBasic2d”

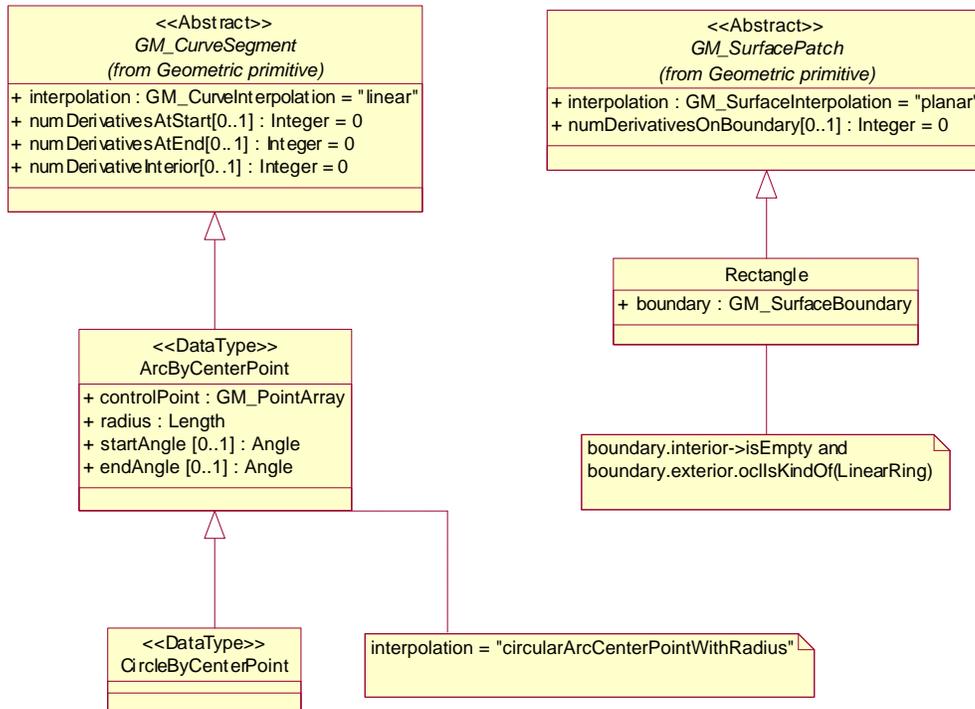

**Figure 64**

An additional subtype of GM\_Surface is added in GML. “Polygon” is a special surface that consists of a single GM\_Polygon patch. Since only a single patch exists, the XML representation of the “Polygon” object element skips the patch level and the exterior and interior boundary properties of the patch are represented as direct properties of the “Polygon”.

In a similar way, “LinearRing” is a simple ring (a GM\_Ring represented by a single line string).

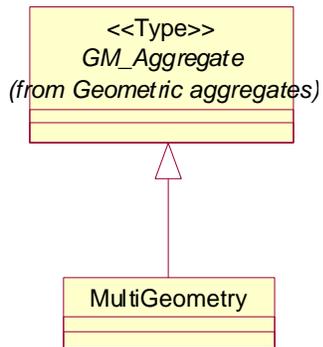

**D.3.9 Package “geometryPrimitives”**

**Figure 65**

The curve segments “ArcByCenterPoint” and “CircleByCenterPoint” as well as the surface patch “Rectangle” have been defined in GML.

### D.3.10 Package “geometryAggregates”

**Figure 66**

GML defines a instantiable geometric aggregate which is not restricted to elements of a single dimension: “MultiGeometry”.

### D.3.11 Package “geometryComplexes”

No additional definitions required.

### D.3.12 Package “topology”

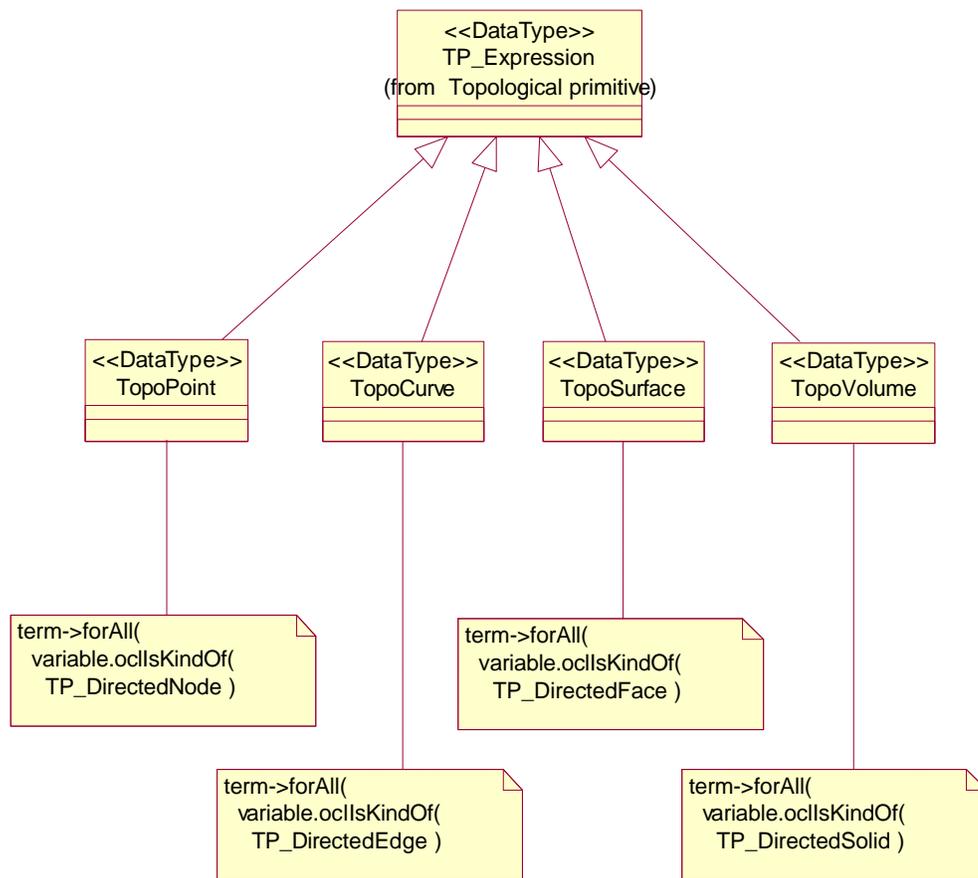

Figure 67

GML defines several data types containing (or referencing) directed topological primitives, one per dimension: “TopoPoint”, “TopoCurve”, “TopoSurface” and “TopoVolume”. These are intended to be used in properties of features.

D.3.13 Package “direction”

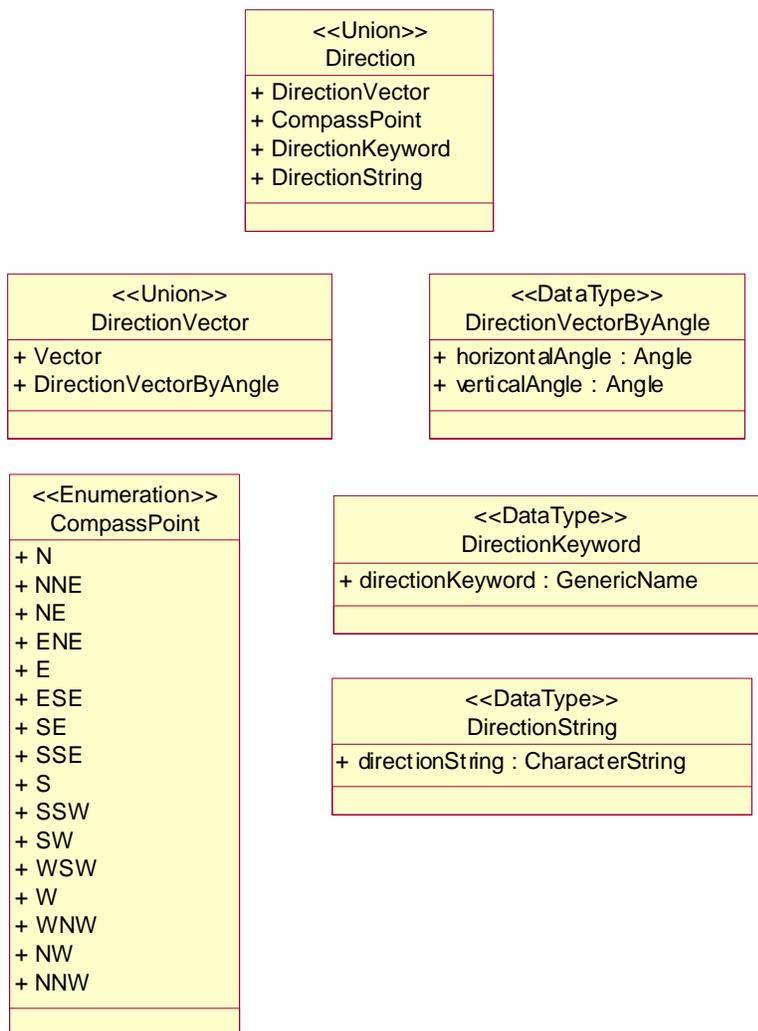

Figure 68

D.3.14 Package “valueObjects”

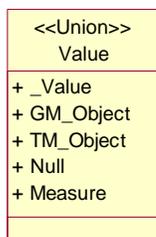

Figure 69

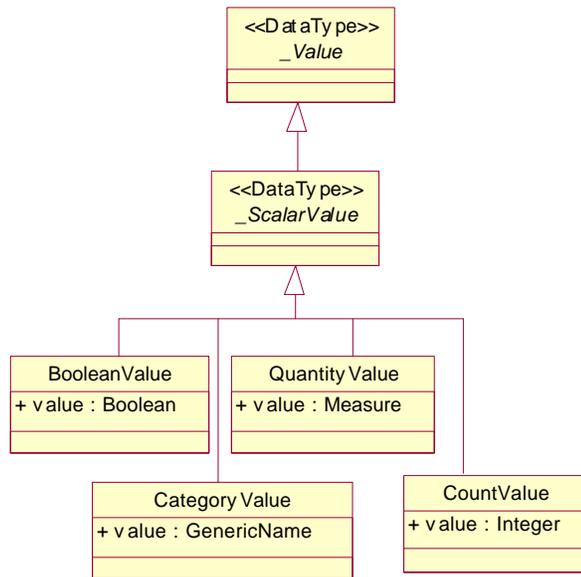

Figure 70

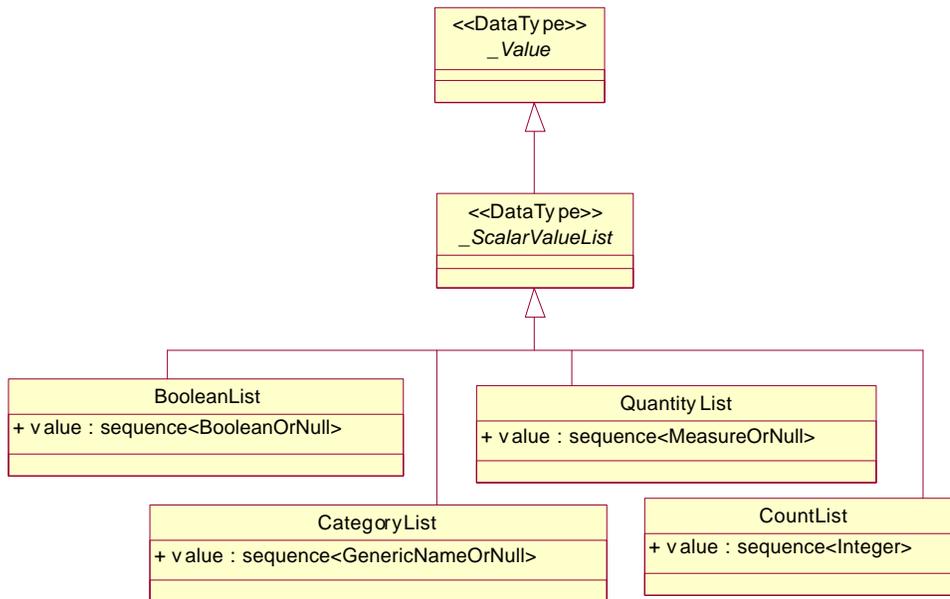

Figure 71

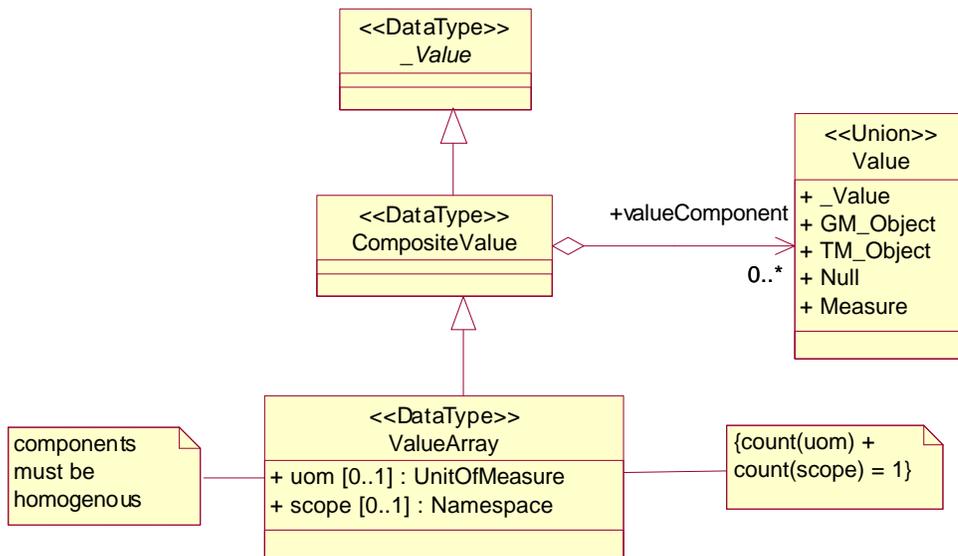

Figure 72

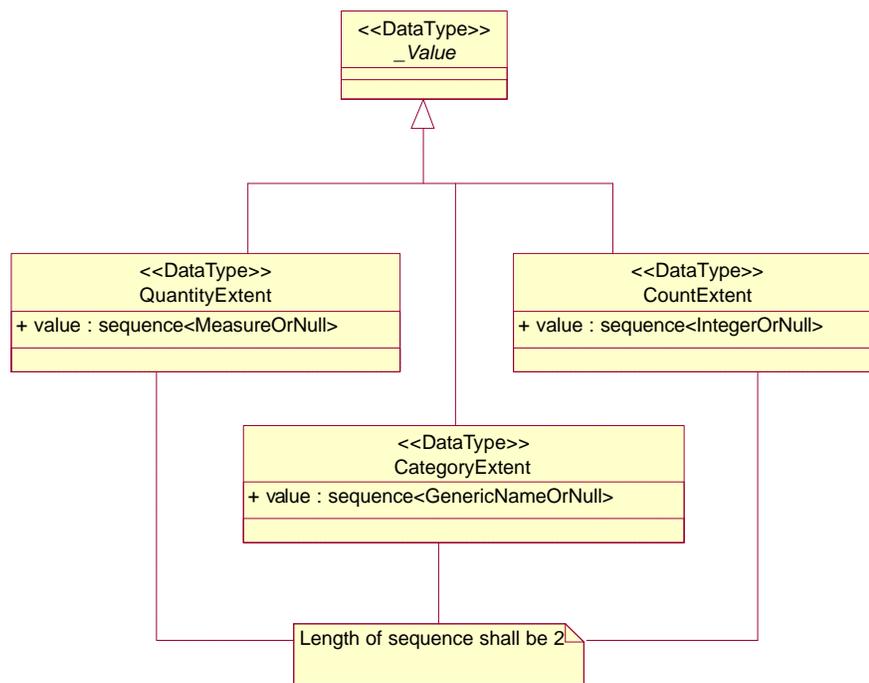

Figure 73

### D.3.15 Package “temporal”

No additional definitions required.

### D.3.16 Package “dynamicFeature”

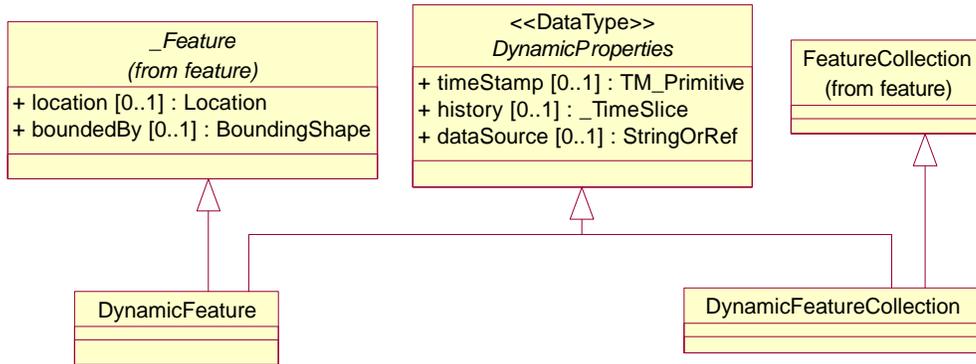

Figure 74

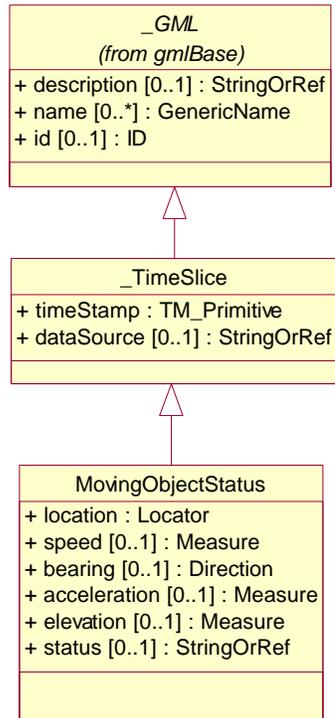

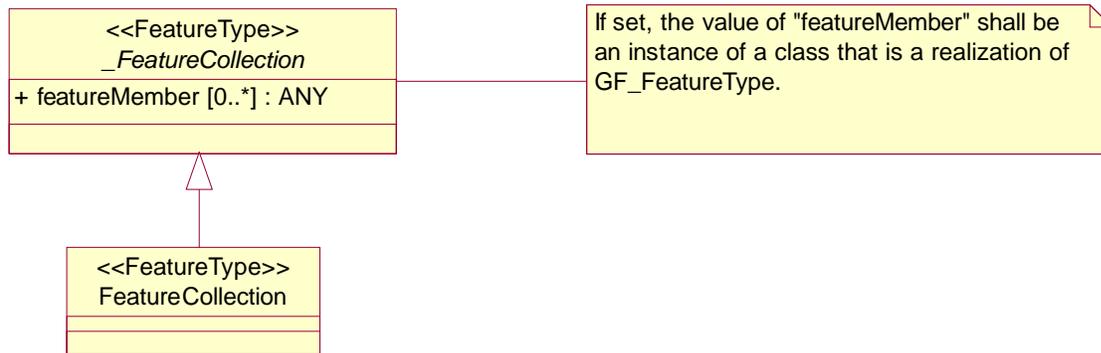

Figure 75

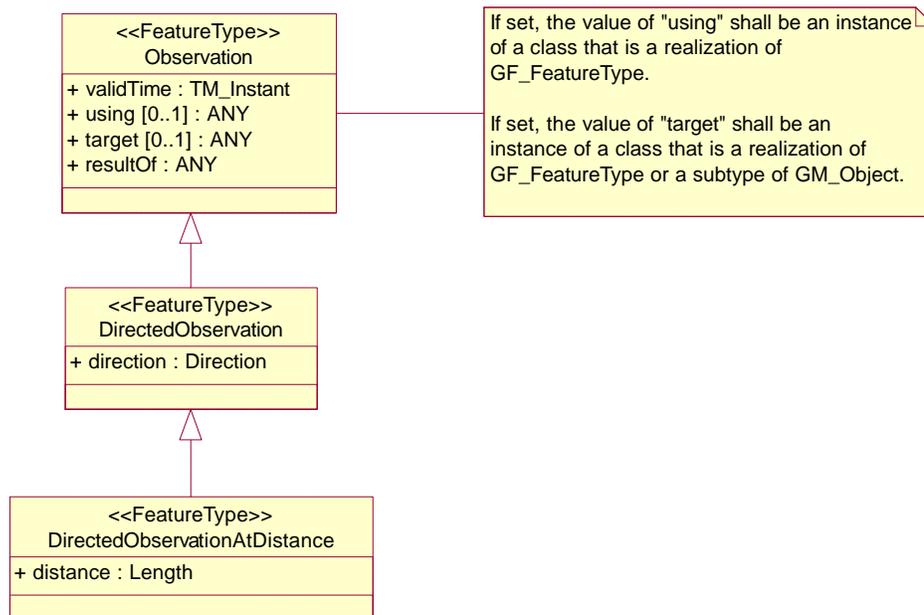

**D.3.17 Package “feature”**

**Figure 76**

Beside the definition of the feature collection type, the GML Schema feature.xsd does not define additional concepts besides those that are part of the mapping from the conceptual schema to the XML Schema implementation (representation of feature types and their predefined properties; see annex E for more details).

**D.3.18 Package “observation”**

**Figure 77**

**D.3.19 Package “grids”**

See clause D.2.10.

### **D.3.20 Package “coverage”**

See clause D.2.10.

### **D.3.21 Packages “coordinateOperations”, “coordinateReferenceSystems”, “coordinateSystems”, “dataQuality”, “datums”, “referenceSystems”**

See clause D.2.6.

### **D.3.22 Package “defaultStyle”**

See clause D.2.9.

## Annex E (normative)

### UML-to-GML Application Schema Encoding Rules

#### E.1 General concepts

The mapping from an ISO 19109 conformant UML Application Schema to the corresponding GML Application Schema is based on a set of encoding rules. These encoding rules are compliant with the rules for GML Application Schemas and are based on ISO DIS 19118.

The rules are derived from the current rules for the GML model and syntax as described in clauses 7 to 23, especially clause 7. The (currently informative) encoding rules of ISO DIS 19118 Annex A are used whenever possible and feasible.

The rules listed in this clause (and the subsequent clause E.2) aim at an automatic mapping from an ISO DIS 19109 / ISO PDS 19103 conformant UML application schema to a GML Application Schema (according to the rules defined in chapter 23). As a result of this automation, the resulting GML Application Schema will not make full use of the capabilities of XML and XML Schema.

These rules do not prescribe that all GML Application Schemas shall be generated by using these rules. All schemas following the rules defined in chapter 23 are valid and conformant GML Application Schemas, whether they are handcrafted, automatically derived from an UML application schema or by some other means.

The schema encoding rules are based on the general idea that the class definitions in the application schema are mapped to type and element declarations in XML Schema, so that the objects in the instance model can be mapped to corresponding element structures in the XML document.

#### E.2 Encoding Rules

##### E.2.1 General encoding requirements

###### E.2.1.1 Application schema

To be a valid input into the mapping the UML Application Schema shall conform to all of the following rules. See ISO DIS 19118 A.2.1 for additional requirements.

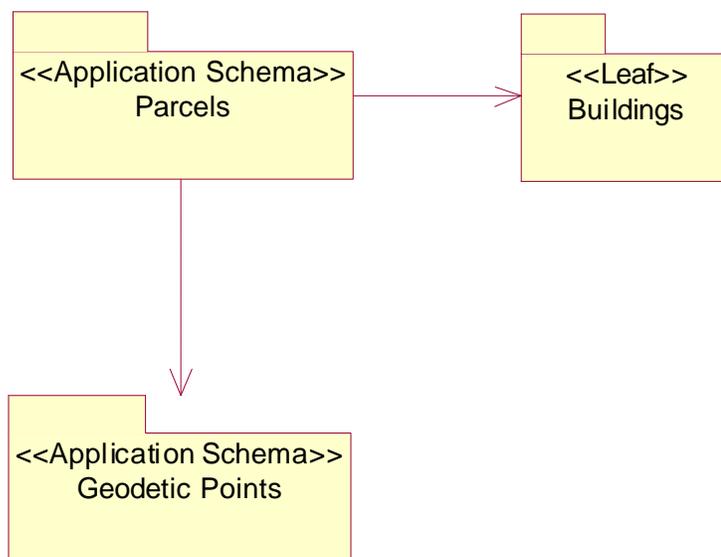

###### E.2.1.1.1 General (Application Schema, Packages)

The UML Application Schema shall conform to the rules defined in ISO DIS 19109 and ISO PDS 19103.

The UML Application Schema shall be represented by a package with the stereotype <<Application Schema>>. This package shall contain (i.e. own directly or indirectly) all UML model elements to be mapped to object types in the GML Application Schema. The UML model shall be complete and not contain external references unless exceptions are explicitly stated below. This allows that predefined classes may be imported from the standardized schemas of the ISO 19100 Harmonized Model.

All package names shall be unique.

Dependencies between packages shall be modelled explicitly. Permission elements with stereotype <<import>> or unspecified dependency elements between packages shall be used to express the dependency of elements in a package from elements in another package. All other dependency elements shall be ignored.

**Figure 78 – Dependency between packages**

The visibility of all UML elements shall be set correctly. Only publicly visible elements shall be part of Application Schemas used for data interchange between applications.

Documentation of the elements in the UML model shall be stored in tagged values “documentation”.

An XML namespace shall be associated with each package and its sub-packages may be specified by a tagged value (tag name “xmlNamespace” for the URI, tag name “xmlNamespaceAbbreviation” for the abbreviation). These tagged values shall be set for the UML Application Schema package. If they are not set, default values shall be used.

The version of a package, if applicable, shall be specified in a tagged value “version”.

#### **E.2.1.1.2 Classes**

All class names within the same XML namespace shall be unique.

Feature types shall be modelled as UML classes with stereotype <<FeatureType>><sup>5</sup>.

Object types shall be modelled as UML classes with stereotype <<ObjectType>>. Object types are types where the instances shall have an identity, but which are not feature types<sup>6</sup>.

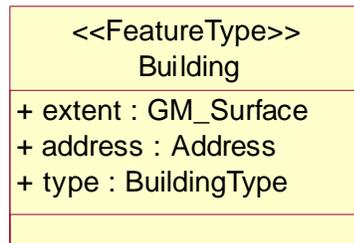

**EXAMPLE** Examples of such types are geometries, topologies, reference systems. Instances of these types can have, for example, a name and an identifier.

<sup>5</sup> Note that it will be easier to identify feature types in UML Application Schemas, if such classes will be tagged with such a stereotype <<FeatureType>>. ISO DIS 19109 currently does not support this stereotype, it is recommended to add such a support in a technical amendment to ISO 19109.

<sup>6</sup> Object types are not considered explicitly in ISO DIS 19109. They appear only as value types of property types.

Abstract object or feature types may have the stereotype <<Abstract>>, but shall be marked as an abstract class (i.e. the UML meta model property “isAbstract” of the class is “true”). The <<Abstract>> stereotype therefore is equivalent to no stereotype.

The same is true for the stereotype <<Leaf>> and classes that are marked as leaf types (i.e. the UML meta model property “isLeaf” of the class is “true”; no subtypes allowed).

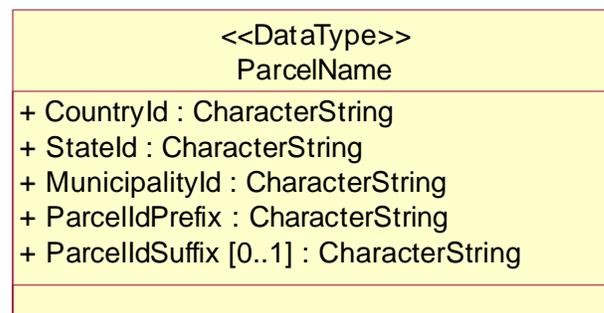

**Figure 79 – A feature type**

Abstract types shall be modelled as UML classes with stereotype <<Interface>> or <<Type>><sup>7</sup>. They may have zero or more operations (these are not mapped to the GML Application Schema), attributes or associations. These classes shall be marked as abstract (the UML meta model property “isAbstract” of the class is “true”).

All subtypes of abstract types shall be either feature, object types or data types.

Data types shall be modelled as UML classes with stereotype <<DataType>>.

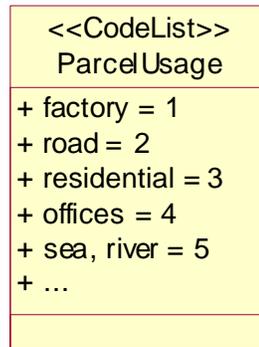

**Figure 80 – A data type**

Enumerations shall be modelled as UML classes with stereotype <<Enumeration>>.

Code lists shall be modelled as UML classes with stereotype <<CodeList>>.

<sup>7</sup> See ISO PDTS 19103 for a discussion of these stereotypes.

**Figure 81 – A code list**

Union types shall be modelled as UML classes with stereotype <<Union>><sup>8</sup>.

UML classes of the ISO 19100 Harmonized Model that are part of the GML profile of the Harmonized Model may be subclassed in the UML Application Schema. Redefinition of properties is not allowed, only the extension of these classes (i.e. additional properties can be added).

All classes with other stereotypes than those mentioned above may be part of the UML Application Schema, but will be ignored.

Generalization relationships are allowed only between

- feature types and features types,
- object types and object types, or
- data types and data types.

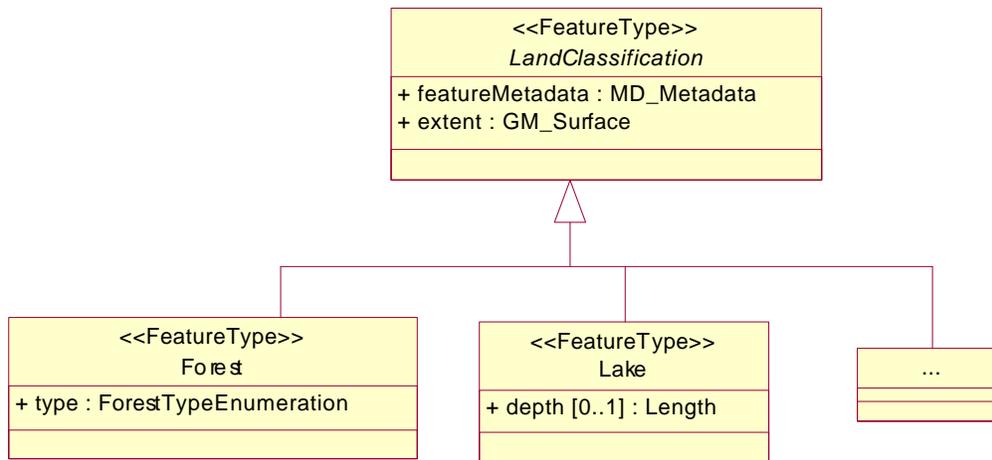

These generalizations shall have no stereotype. All generalization relationships with other stereotypes will be ignored. The discriminator property of the UML generalization shall be blank.

If a class is a specialization of another class, then this class shall have only one supertype (no support for multiple inheritance).

All classes shall have a stereotype specifying the meaning of the class. Classes without a stereotype are treated as feature types<sup>9</sup>.

<sup>8</sup> Note that <<Union>> is currently not defined in ISO PDTS 19103 anymore. However, since this stereotype is used quite frequently in ISO 19100 models, it is supported by these encoding rules. The same is true for <<BasicType>>.

<sup>9</sup> If ISO 19109 is amended as proposed above, the default interpretation should be changed to object type.

**Figure 82 – Generalization relationship between feature types**

#### E.2.1.1.3 Attributes

Every UML attribute of an abstract type, feature type, object type, data type or union type shall have a name and a type. If its multiplicity is not “1”, the multiplicity shall be specified explicitly. An initial value may be specified for attributes with a number, string or enumeration type.

The type shall either be a predefined type (see clause E.2.1.1.5) or a class defined in the UML model. An attribute with a type that is a feature or object type is treated like an association navigable only towards the association end of the target type.

Every UML attribute of an enumeration class shall have a name. The type information is left empty. No multiplicity, ordering or initial value information shall be attached to the attribute.

Every UML attribute of a code list class shall have a name. The type information is left empty. No multiplicity or ordering information shall be attached to the attribute. An initial value may be specified to document a code for the code list value. If it is omitted, the value (i.e. the attribute name) is used as the code.

#### E.2.1.1.4 Associations and association ends

Every UML association shall be an association with exactly two association ends. Both association ends shall connect to a feature or data type and shall have no stereotype or the stereotype <<association>> (or the whole association will be ignored).

The rules for association ends are:

- If an association end is navigable it shall be marked as such and shall have a name. An association end with no name shall be ignored, even if it marked as navigable.
- If the multiplicity of an association end is not “0..\*”, the multiplicity shall be given explicitly.
- The aggregation kind shall be specified explicitly if it is not “none”.
- If the target class of an association end is a data type, then the aggregation kind shall be “composition”.

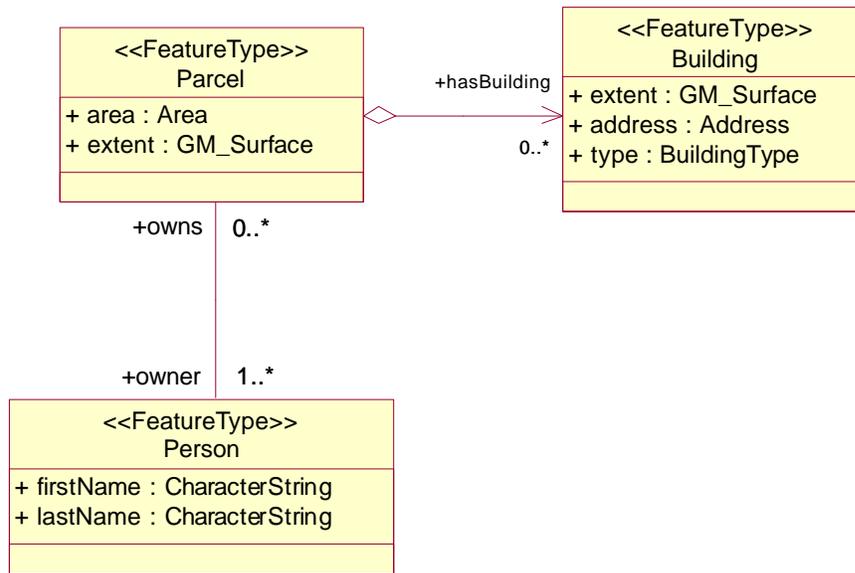

Figure 83 – Associations

#### E.2.1.1.5 Predefined Types

The following predefined types from ISO PDTS 19103 are treated as “basic types” in the sense of ISO DIS 19118 Annex A (i.e. a canonical XML Encoding is attached to them). These basic types are assumed to be pre-defined basic types and shall not be explicitly defined in the UML model:

- Character
- CharacterString
- Integer
- Real
- Decimal
- Number
- Vector
- Date
- Time
- DateTime
- Boolean
- Sign
- Fraction
- GenericName
- LocalName

- ScopedName
- Length
- Distance
- Angle
- Velocity
- Scale
- Area
- Volume
- Measure
- UnitOfMeasure

#### **E.2.1.1.6 OCL Constraints**

All OCL constraints are ignored. The assessment of the validity of the instance model with respect to these constraints is the task of the application processing the GML instances.

NOTE The Schematron language may be used to express OCL constraints as part of the XML Schema representing the GML Application Schema.

#### **E.2.1.1.7 Other information**

All other information in the UML Application Schema is not used in the encoding rules and is ignored.

#### **E.2.1.2 Character repertoire and languages**

“UTF-8” shall be used as the character encoding of the XML Schema files (with the associated character repertoire) in accordance with the XML specification.

#### **E.2.1.3 Exchange metadata**

Exchange metadata can be specified for every Feature or Feature Collection in a GML instance document (by using the „gml:metaDataProperty“ element and the ISO 19139 XML Schema implementation specification of ISO 19115). No specific schema for the exchange metadata is added to the GML application schema.

#### **E.2.1.4 Dataset and object identification**

Unique identifiers according to XML's ID mechanism are used to identify objects.

#### **E.2.1.5 Update mechanism**

No explicit update mechanism is defined for the features defined in the GML Application Schema. It is assumed that other mechanisms are used to update a data store.

NOTE An example is the “Transaction” operation of the OpenGIS<sup>®</sup> Web Feature Service Implementation Specification.

### **E.2.2 Input data structure**

See ISO DIS 19118 A.3 for a description of the input data structure.

## E.2.3 Output data structure

This encoding rule is based on the XML Recommendation 1.0 and the XML Linking Language (XLink) Version 1.0. The schema for the output data structure that governs the structure of the exchange format shall be a (set of) valid XML Schema(s) according to XML Schema 1.0 and the Rules for Application Schemas (see clause 23).

The XML Schema conversion rules are defined in the following clause.

## E.2.4 Conversion rules

### E.2.4.1 General concepts

The schema conversion rules define how XML Schema documents (XSDs) shall be derived from an ISO 19109 application schema expressed in UML. A number of general rules are defined in the following clauses to describe the mapping from an UML model that follows the guidelines described in the previous clause.

NOTE In this annex the namespace "xsd:" is used to refer to the namespace of XML Schema, which is "http://www.w3.org/2001/XMLSchema". The namespace "gml:" refers to the namespace of GML, which is "http://www.opengis.net/gml".

The rules are based on the current rules for the GML model and syntax as described in clauses 7 to 23 (especially clauses 7, 8 and 23) and also on the encoding rules of ISO DIS 19118 Annex A.

The schema encoding rules are based on the general idea that the class definitions in the UML application schema are mapped to type and element declarations in XML Schema, so that the objects in the instance model can be mapped to corresponding element structures in the XML document.

The following table gives an overview:

**Table 18 – Schema encoding overview**

Table: UML → GML Application Schema Overview	
UML Application Schema	GML Application Schema
Package	One XML Schema document per package (default mapping)
<<DataType>>	complexType, property type and global element
<<Enumeration>>	Restriction of xsd:string with enumeration values
<<CodeList>>	Union of an enumeration and a pattern (default mapping, an alternative mapping is a reference to a dictionary)
<<Union>>	Choice group whose members are GML Objects or Features, or objects corresponding to DataTypes
<<ObjectType>>	Direct/indirect extension of gml:AbstractGMLType, property type & global element
<<FeatureType>>	Direct/indirect extension of gml:AbstractFeatureType, property type & global element
No stereotype	Direct/indirect extension of gml:AbstractFeatureType, property type & global element
<<Type>>	Direct/indirect extension of gml:AbstractGMLType, property type & global element
Operations	Not encoded
Attribute	local xsd:element, the type is either a property type (if the type is a complex type) or a simple type.

Association role	local xsd:element, the type is always a property type (only named and navigable roles)
General OCL constraints	Not encoded

The multiplicity of attributes and association roles is mapped to „minOccurs“ and „maxOccurs“ attributes in <xsd:element> declarations. The detailed mapping rules are described below.

#### E.2.4.2 UML Packages

The default mapping is that one XML Schema file is generated per package. Name and XML namespace are determined by the name and – if set – the tagged values of the package (see E.2.1). Alternatively, several packages may be mapped to the same XML Schema file. All packages shall be associated with the same XML namespace.

The schema file contains all the XML Schema definitions resulting from the UML classes directly owned by the package(s).

The dependencies of the packages and the package hierarchy are used to determine the required imports and includes of other XML Schema files.

The following tagged values of packages are evaluated:

- xmlNamespace and xmlNamespaceAbbreviation → URI (e.g. “http://www.myorg.com/myns”) and abbreviation (e.g. “myns”) of the target namespace of the XML Schema document.
- version → version attribute of the root element of the XML Schema document (default “unknown”).

EXAMPLE Mapping the information from Figure 78 may result in:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema targetNamespace="http://www.myorg.com/parcels" xmlns="http://www.w3.org/2001/XMLSchema"
xmlns:gml="http://www.opengis.net/gml" xmlns:gp="http://www.myorg.com/geodeticPoints"
xmlns:pcl="http://www.myorg.com/parcels" xmlns:iso19115="http://www.iso19115.org/iso19115/"
xmlns:xlink="http://www.w3.org/1999/xlink" elementFormDefault="qualified" version="2003-07-20">
  <include schemaLocation="Buildings.xsd"/>
  <import namespace="http://www.myorg.com/geodeticPoints" schemaLocation="GeodeticPoints.xsd"/>
  <import namespace="http://www.opengis.net/gml" schemaLocation="base/gml3.xsd"/>
  <!-- ... -->
</schema>
```

#### E.2.4.3 UML Classes (general rules)

Allowed stereotypes for UML classes are: no stereotype, <<FeatureType>>, <<ObjectType>>, <<Type>>, <<DataType>>, <<Union>>, <<Abstract>>, <<CodeList>>, <<Enumeration>>, <<Leaf>>, <<Interface>>. All classes will be mapped to the corresponding class category. All UML classes with other stereotypes will be ignored.

All UML classes shall have zero or one supertype.

All UML classes are mapped to named types. A suffix “Type” is added to the name of the type.

#### E.2.4.4 UML Classes (basic types)

The following basic types from the ISO PDTs 19103 profile of GML are predefined and can be referenced in an UML Application Schema. The mapping to a built-in type of XML Schema (“xsd:”) or GML (“gml:”) is specified.

- CharacterString → xsd:string
- Integer → xsd:integer
- Real → xsd:double
- Decimal → xsd:double
- Number → xsd:double
- Vector → gml:VectorType
- Date → xsd:date
- Time → xsd:time
- DateTime → xsd:dateTime
- Boolean → xsd:boolean
- GenericName → gml:CodeType
- LocalName → gml:CodeType
- ScopedName → gml:CodeType
- Length → gml:LengthType
- Distance → gml:LengthType
- Angle → gml:AngleType
- Velocity → gml:SpeedType
- Scale → gml:ScaleType
- Area → gml:AreaType
- Volume → gml:VolumeType
- Measure → gml:MeasureType
- Sign → gml:SignType
- UnitOfMeasure → gml:UnitOfMeasureType

In addition, the following predefined can be referenced in the UML Application Schema and are mapped to a built-in type of XML Schema (“xsd:”) or GML (“gml:”) as follows:

- booleanOrNull → gml:booleanOrNull
- sequence<booleanOrNull> → gml:booleanOrNullList
- stringOrNull → gml:stringOrNull
- sequence<stringOrNull> → gml:stringOrNullList
- NameOrNull → gml:NameOrNull
- sequence<NameOrNull> → gml:NameOrNullList

- doubleOrNull → gml:doubleOrNull
- sequence<DoubleOrNull> → gml:doubleOrNullList
- integerOrNull → gml:integerOrNull
- sequence<integerOrNull> → gml:integerOrNullList
- measureOrNull → gml:MeasureOrNull
- sequence<measureOrNull> → gml:MeasureOrNullList
- Coordinates → gml:CoordinatesType
- Null → gml:NullType

#### E.2.4.4 UML Classes (data types)

UML classes with stereotype <<DataType>> are mapped to XML Schema complex types. If the class has not supertype it is a non-derived type in XML Schema, otherwise it extends its supertype which shall not be derived from gml:AbstractGMLType (directly or indirectly). Abstract superclasses without any attribute or navigable association role are ignored.

Global XML elements with appropriate settings for name (name of the UML class), type (name of the UML class plus "Type"), abstractness (if the class is abstract) and substitution groups (the name of the superclass) may be defined for these classes.

A named complex type shall be created for these classes (carrying the name of the class with a "PropertyType" suffix). The type follows the pattern for association properties as defined in GML (see clause 7.5.3), but without allowing Xlink attributes.

#### EXAMPLE

```
<complexType name="PoleinfoType">
  <sequence>
    <element name="height" type="gml:LengthType"/>
    <element name="measurementDate" type="date"/>
  </sequence>
</complexType>
```

an optionally

```
<element name="Poleinfo" type="ex:PoleinfoType"/>
<complexType name="PoleinfoPropertyType">
  <sequence>
    <element ref="ex:Poleinfo"/>
  </sequence>
</complexType>
```

or

```
<complexType name="PoleinfoPropertyType">
  <sequence>
    <element name="Poleinfo" type="ex:PoleinfoType"/>
  </sequence>
</complexType>
```

#### E.2.4.5 UML Classes (feature types)

UML classes with stereotype <<FeatureType>>, without stereotype or one of the stereotypes <<Abstract>>/<<Interface>> derive directly or indirectly from gml:AbstractFeatureType. If the class is a class without supertype it extends directly gml:AbstractFeatureType, otherwise it extends its supertype which shall be derived from gml:AbstractFeatureType (again, directly or indirectly).

There is one special case: A feature type with no supertype and exactly one aggregation or composition to another class may be mapped to a feature collection (i.e. become a restriction of gml:AbstractFeatureCollectionType). In this case, the association role shall be defined as substitutable for gml:featureMember. The name of the global element would be a combination of the class and the property name to guarantee uniqueness in the XML namespace.

- Global XML elements with appropriate settings for name (name of the UML class), type (name of the UML class plus "Type"), abstractness (true, if the class is abstract) and substitution group (the name of the supertype or "gml:\_Feature") are defined for these classes.
- A named complex type may be created for these classes (carrying the name of the class with a "PropertyType" suffix). The type follows the pattern for association properties as defined in GML (see clause 7.5.3).
- A named complex type may be created for these classes (carrying the name of the class with a "PropertyByValueType" suffix). The type is a profile of the pattern for association properties as defined in GML restricted to the "by value" form (again, see clause 7.5.3).

EXAMPLE Mapping "Building" from Figure 79 may be mapped to:

```
<complexType name="BuildingType">
  <complexContent>
    <extension base="gml:AbstractFeatureType">
      <sequence>
        <element name="extent" type="gml:SurfacePropertyType"/>
        <element name="address" type="pcl:AddressPropertyType"/>
        <element name="type" type="pcl:BuildingTypeType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

<complexType name="BuildingPropertyType">
  <sequence>
    <element ref="pcl:Building" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

<complexType name="BuildingPropertyByValueType">
  <sequence>
    <element ref="pcl:Building"/>
  </sequence>
</complexType>

<element name="Building" type="pcl:BuildingType" substitutionGroup="gml:_Feature"/>
```

#### E.2.4.6 UML Classes (object types)

UML classes with stereotype <<ObjectType>> or <<Type>> derive directly or indirectly from gml:AbstractGMLType. If the class is a class without supertype it extends directly gml:AbstractGMLType, otherwise it extends its supertype which shall be derived from gml:AbstractGMLType (again, directly or indirectly), but not from gml:AbstractFeatureType (again, directly or indirectly).

- Global XML elements with appropriate settings for name (name of the UML class), type (name of the UML class plus “Type”), abstractness (true, if the class is abstract) and substitution group (the name of the supertype or “gml\_GML”) are defined for these classes.
- A named complex type may be created for these classes (carrying the name of the class with a “PropertyType” suffix). The type follows the pattern for association properties as defined in GML (see clause 7.5.3).
- A named complex type may be created for these classes (carrying the name of the class with a “PropertyByValueType” suffix). The type is a profile of the pattern for association properties as defined in GML restricted to the “by value” form (again, see clause 7.5.3).

## EXAMPLE

```

<element name="Ellipse" type="ex:EllipseType" substitutionGroup="gml:_CurveSegment"/>

<complexType name="EllipseType">
  <complexContent>
    <extension base="gml:AbstractCurveSegmentType">
      <sequence>
        <element name="center" type="gml:DirectPosition"/>
        <element name="semiminor" type="gml:VectorType"/>
        <element name="semimajor" type="gml:VectorType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>

```

**E.2.4.7 UML Classes (enumerations)**

UML classes with stereotype <<Enumeration>> are mapped to XML Schema simple types. The base type is “string”, the domain of values is restricted to the allowed set of literal values as specified by the attribute names of the UML class.

## EXAMPLE

```

<simpleType name="SignType">
  <restriction base="string">
    <enumeration value="-"/>
    <enumeration value="+"/>
  </restriction>
</simpleType>

```

**E.2.4.8 UML Classes (code lists)**

UML classes with stereotype <<CodeList>> are – in principle – mapped like enumerations, but with an added value (<pattern value='other: \w{2,}'/>) that allows for any text value beside the predefined values; these free values are prefixed with “other: ”.

If codes are specified for code list values, either only the code or both the code and the text value shall be represented as enumerated values.

An encoded code value shall be qualified with an appinfo annotation (source “urn:x-gml:codelistValue”) specifying the text value of the enumerated value.

EXAMPLE The code list “ParcelUsage” from Figure 81 may be represented as:

```

<simpleType name="ParcelUsageType">
  <union memberTypes="pcl:ParcelUsageEnumerationType pcl: ParcelUsageOtherType"/>
</simpleType>

```

```

<simpleType name="ParcelUsageEnumerationType">
  <restriction base="string">
    <enumeration value="1">
      <annotation>
        <appinfo source="urn:x-gml:codelistValue">factory </appinfo>
      </annotation>
    </enumeration>
    <enumeration value="2">
      <annotation>
        <appinfo source="urn:x-gml:codelistValue">road</appinfo>
      </annotation>
    </enumeration>
    <enumeration value="3">
      <annotation>
        <appinfo source="urn:x-gml:codelistValue">residential</appinfo>
      </annotation>
    </enumeration>
    <enumeration value="4">
      <annotation>
        <appinfo source="urn:x-gml:codelistValue">offices</appinfo>
      </annotation>
    </enumeration>
    <enumeration value="5">
      <annotation>
        <appinfo source="urn:x-gml:codelistValue">sea, river</appinfo>
      </annotation>
    </enumeration>
    <enumeration value="factory"/>
    <enumeration value="road"/>
    <enumeration value="residential"/>
    <enumeration value="offices"/>
    <enumeration value="sea, river"/>
  </restriction>
</simpleType>
<simpleType name="ParcelUsageOtherType">
  <restriction base="string">
    <pattern value="other: \w{2,}"/>
  </restriction>
</simpleType>

```

Alternatively, gml:Dictionaryes can be used to represent code lists.

#### E.2.4.9 UML Classes (unions)

UML classes with stereotype <<Union>> are mapped as XML Schema complex types. These classes are mapped like data types (see E.2.4.4), but instead of a <xsd:sequence> of the properties, a <xsd:choice> is used so that exactly one of the properties can be specified in an instance of an union.

EXAMPLE

```

<complexType name="RemoteResourceType">
  <choice>
    <element name="name" type="string"/>
    <element name="uri" type="anyURI"/>
  </choice>
</complexType>

```

#### E.2.4.10 UML Attributes and Association roles

An UML attribute or association role of an object or feature type is mapped to a local element with the same name in the complex type defining the content model of the object or feature type. The minOccurs and maxOccurs attributes are set according to the definitions in the UML model (see ISO DIS 19118 Annex A for details of the mapping). The type depends on the type of the value of the property in UML:

If the type of the value of the property is of simple content, then the type is used directly.

EXAMPLE `<element name="count" type="integer"/>`

If the type of the value of the property is of complex content, then a property type shall be used. The default encoding of the property type allows both the by-value or by-reference representation.

If the encoded property is an association end and the other association end of the association is also encoded in the GML Application Schema, the property name of the other association end shall be encoded in another appinfo annotation (source "urn:x-gml:reverseProperty").

EXAMPLE By-reference or by-value:

```
<element name="owner" type="ex:PersonPropertyType" minOccurs="0">
  <annotation>
    <appinfo source="urn:x-gml:reverseProperty">owns</appinfo>
  </annotation>
</element>
<complexType name="PersonPropertyType">
  <sequence>
    <element ref="ex:Person" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>
```

or

```
<element name="owner" minOccurs="0">
  <annotation>
    <appinfo source="urn:x-gml:reverseProperty">owns</appinfo>
  </annotation>
  <complexType>
    <sequence>
      <element ref="ex:Person" minOccurs="0"/>
    </sequence>
    <attributeGroup ref="gml:AssociationAttributeGroup"/>
  </complexType>
</element>
```

Alternatively, the property type may support only one of the representations, by-value or by-reference.

EXAMPLE By-value only:

```
<element name="owner" type="ex:PersonPropertyByValueType" minOccurs="0"/>
<complexType name="PersonPropertyByValueType">
  <sequence>
    <element ref="ex:Person"/>
  </sequence>
</complexType>
```

or

```
<element name="owner" minOccurs="0">
  <complexType>
    <sequence>
      <element ref="ex:Person"/>
    </sequence>
  </complexType>
</element>
```

If only the by-reference representation shall be supported, then the property element shall be qualified with an appinfo annotation (source "urn:x-gml:targetElement") specifying the qualified element name of the target type.

If the encoded property is an association end and the other association end of the association is also encoded in the GML Application Schema, the property name of the other association end shall be encoded in another appinfo annotation (source "urn:x-gml:reverseProperty").

EXAMPLE By-reference only:

```
<element name="owner" type="gml:ReferenceType" minOccurs="0">
  <annotation>
    <appinfo source="urn:x-gml:targetElement">Person</appinfo>
    <appinfo source="urn:x-gml:reverseProperty">owns</appinfo>
  </annotation>
</element>
```

Depending on the encoding of the class, an UML attribute of a code list or enumeration type is mapped to an element with either a string value (value domain: values of the enumeration or code list) or a URI pointing to the corresponding dictionary entry.

EXAMPLE The code list "BuildingType" may be represented as:

```
<element name="type" type="ex:BuildingTypeType"/>
```

or

```
<element name="type" type="gml:ReferencesType">
  <annotation>
    <appinfo source="urn:x-gml:referencedCodelist">BuildingType</appinfo>
  </annotation>
</element>
```

If an UML attribute or UML association is redefined (i.e. a subclass contains an attribute with the same name as in a supertype) then the type derivation takes place in two steps. First a restriction of the superclass is defined by a restriction of the type representing the superclass restricting the redefined attributes and/or specialized associations (the rules for restrictions in XML shall be adhered to by the UML Application Schema). Then this restricted type is extended to include all the additional properties of the subclass. An XML element is generated for both types. The intermediate type and its element will never be instantiated and are both abstract (abstract="true"). The name of the intermediate type shall be the name of the instantiable type where the suffix "Type" is replaced by "RestrictionType".

#### E.2.4.11 Documentation

Tagged values "documentation" from elements in the UML model are mapped to annotation/documentation elements in the XML Schema files.

EXAMPLE

```
<element name="curveProperty" type="gml:CurvePropertyType">
  <annotation>
    <documentation>This property element either references a curve via the XLink-attributes or contains the
    curve element. curveProperty is the predefined property which can be used by GML Application Schemas whenever a
    GML Feature has a property with a value that is substitutable for _Curve.</documentation>
  </annotation>
</element>
```

#### E.2.4.12 Imported Classes from the ISO 19100 Harmonized Model

In addition to the rules defined above, the following rules apply when the UML Application Schema imports classes from the ISO 19100 Harmonized Model.

Classes from the ISO 19100 Harmonized Model that are implemented by the GML Schemas shall be recognized. The use of ISO 19100 classes shall be conformant with ISO DIS 19109. The mapping of the

relevant classes from the ISO 19100 harmonized model according to ISO DIS 19109 is shown in the following table.

Table 19

ISO 19100 class	Type of the GML property (attribute or association end)	GML base type (specialized class)	GML substitution element (specialized class)
GM_Object	gml:GeometryPropertyType	gml:AbstractGeometryType	gml:_Geometry
GM_Primitive	gml:GeometricPrimitivePropertyType	gml:AbstractGeometricPrimitiveType	gml:_GeometricPrimitive
GM_Position	gml:geometricPositionGroup (group)	-	-
GM_PointArray	gml:geometricPositionListGroup (group)	-	-
GM_Point	gml:PointPropertyType	gml:PointType	gml:Point
GM_Curve	gml:CurvePropertyType	gml:AbstractCurveType	gml:_Curve
GM_Surface	gml:SurfacePropertyType	gml:AbstractSurfaceType	gml:_Surface
GM_Solid	gml:SolidPropertyType	gml:AbstractSolidType	gml:_Solid
GM_CompositePoint	gml:PointPropertyType	gml:PointType	gml:Point
GM_CompositeCurve	gml:CompositeCurveType	gml:CompositeCurveType	gml:CompositeCurve
GM_CompositeSurface	gml:CompositeSurfaceType	gml:CompositeSurfaceType	gml:CompositeSurface
GM_CompositeSolid	gml:CompositeSolidType	gml:CompositeSolidType	gml:CompositeSolid
GM_Complex	gml:GeometricComplexPropertyType	gml:GeometricComplexType	gml:GeometricComplex
GM_Aggregate	gml:MultiGeometryPropertyType	gml:MultiGeometryType	gml:MultiGeometry
GM_MultiPoint	gml:MultiPointPropertyType	gml:MultiPointType	gml:MultiPoint
GM_MultiCurve	gml:MultiCurvePropertyType	gml:MultiCurveType	gml:MultiCurve
GM_MultiSurface	gml:MultiSurfacePropertyType	gml:MultiSurfaceType	gml:MultiSurface
GM_MultiSolid	gml:MultiSolidPropertyType	gml:MultiSolidType	gml:MultiSolid
GM_MultiPrimitive	gml:MultiGeometryPropertyType	gml:MultiGeometryType	gml:MultiGeometry
TP_Node	gml:DirectedNodePropertyType	gml:DirectedNodeType	gml:DirectedNode
TP_Edge	gml:DirectedEdgePropertyType	gml:DirectedEdgeType	gml:DirectedEdge
TP_Face	gml:DirectedFacePropertyType	gml:DirectedFaceType	gml:DirectedFace
TP_Solid	gml:DirectedTopoSolidPropertyType	gml:DirectedTopoSolidType	gml:DirectedTopoSolid
TP_DirectedNode	gml:DirectedNodePropertyType	gml:DirectedNodeType	gml:DirectedNode
TP_DirectedEdge	gml:DirectedEdgePropertyType	gml:DirectedEdgeType	gml:DirectedEdge
TP_DirectedFace	gml:DirectedFacePropertyType	gml:DirectedFaceType	gml:DirectedFace
TP_DirectedSolid	gml:DirectedTopoSolidPropertyType	gml:DirectedTopoSolidType	gml:DirectedTopoSolid
TP_Complex	gml:TopoComplexMemberType	gml:TopoComplexType	gml:TopoComplex
TM_Instant	gml:TimeInstantPropertyType	gml:TimeInstantType	gml:TimeInstant
TM_Period	gml:TimePeriodPropertyType	gml:TimePeriodType	gml:TimePeriod
TM_TopologicalComplex	gml:TimeTopologyComplexPropertyType	gml:TimeTopologyComplexType	gml:TimeTopologyComplex
TM_Node	gml:TimeNodePropertyType	gml:TimeNodeType	gml:TimeNode
TM_Edge	gml:TimeEdgePropertyType	gml:TimeEdgeType	gml:TimeEdge
SI_LocationInstance	gml:LocationKeyword or gml:LocationString	-	-
<i>types defined in ISO 19115:2003</i>	<i>Property types encapsulating the object and data types from ISO WD 19139 shall be used</i>	-	-

### E.3 Example <informative>

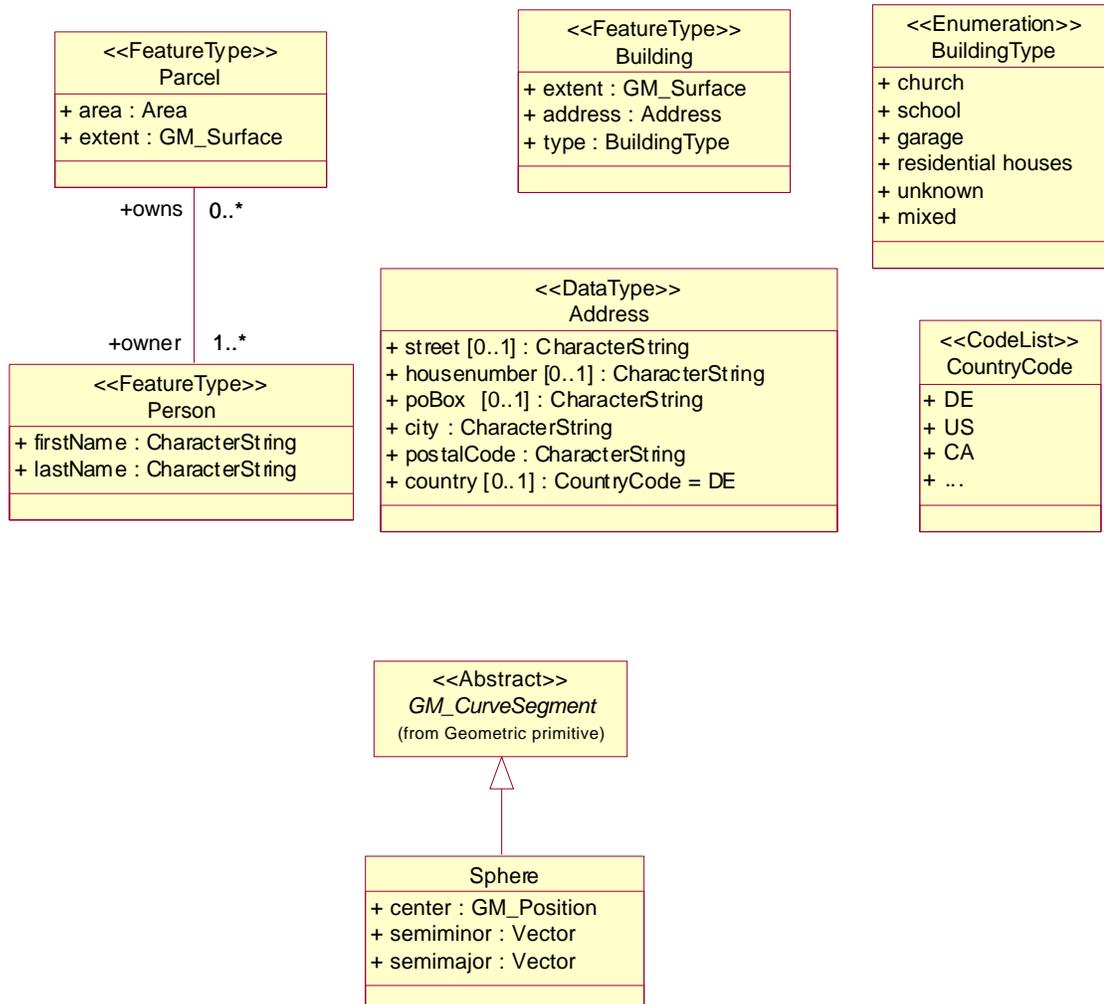

Figure 84 – Example Application Schema

The application schema shown in Figure 84 may be encoded as

```

<?xml version="1.0" encoding="UTF-8"?>
<schema targetNamespace="http://www.someorg.de/example" xmlns="http://www.w3.org/2001/XMLSchema"
xmlns:ex="http://www.someorg.de/example" xmlns:gml="http://www.opengis.net/gml" elementFormDefault="qualified"
version="1.0">
  <!-- ===== -->
  <import namespace="http://www.opengis.net/gml" schemaLocation="./gmlProfile.xsd"/>
  <import namespace="http://www.w3.org/1999/xlink" schemaLocation="./xlinks.xsd"/>
  <!-- ===== -->
  <element name="Parcel" substitutionGroup="gml:_Feature">
    <complexType>
      <complexContent>
        <extension base="gml:AbstractFeatureType">
          <sequence>
            <element name="area" type="gml:AreaType"/>
          </sequence>
        </extension>
      </complexContent>
    </complexType>
  </element>
  </schema>
  
```

```

        <element name="extent" type="gml:SurfacePropertyType"/>
        <element name="owner" type="ex:PersonPropertyType">
          <annotation>
            <appinfo source="urn:x-gml:reverseProperty">owns</appinfo>
          </annotation>
        </element>
      </sequence>
    </extension>
  </complexContent>
</complexType>
</element>
<complexType name="ParcelPropertyType">
  <sequence>
    <element ref="ex:Parcel" minOccurs="0"/>
  </sequence>
  <attributeGroup ref="gml:AssociationAttributeGroup"/>
</complexType>

        <group ref="gml:geometricPositionGroup"/>
        <element name="semiminor" type="gml:VectorType"/>
        <element name="semimajor" type="gml:VectorType"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
</schema>

```

## Annex F (normative)

### GML-to-UML Application Schema Encoding Rules

#### F.1 General concepts

The mapping from a GML application schema to an ISO 19109 conformant UML application schema is based on a set of encoding rules. These encoding rules are compliant with the rules for GML application schemas as described in clauses 7 through 23, especially clauses 7 and 8.

The rules listed in this clause (and the subsequent clause F.2) aim at an automatic mapping from a GML application schema to an ISO DIS 19109 / ISO PDTS 19103 conformant UML application schema.

These rules do not prescribe that all GML Application Schemas shall be generated to fulfill the encoding requirements documented in this annex. All schemas following the rules defined in chapter 23 are valid and conformant GML Application Schemas.

This annex shall be used if there is a requirement in the application domain to derive an ISO 19109 conformant UML Application Schema from a GML Application Schema.

The XML namespace abbreviation "xsd" is used to refer to the namespace of XML Schema, which is "http://www.w3.org/2001/XMLSchema".

The XML namespace abbreviation "gml" refers to the XML namespace of GML, which is "http://www.opengis.net/gml".

In addition, GML imports definitions from the following namespaces:

The XML namespace abbreviation "xlink" refers to the XML namespace for xlink, which is "http://www.w3.org/1999/xlink".

The XML namespace abbreviation "smil20" refers to the XML namespace for SMIL (Synchronized Multimedia Integration Language), which is "http://www.w3.org/2001/SMIL20".

The XML namespace abbreviation "smil20lang" refers to the XML namespace for SMIL language, which is "http://www.w3.org/2001/SMIL20/Language".

The term "GML namespaces" is used below to refer to the namespaces "gml", "xlink", "smil20", and "smil20lang".

#### F.2 Encoding Rules

##### F.2.1 General encoding requirements

###### F.2.1.1 General remarks

The schema encoding rules are based on the general idea that the corresponding type and element declarations in XML Schema are mapped to class definitions in the UML application schema, so that element structures in the XML document can be mapped to the objects in the instance model.

## F.2.1.2 GML schema

### F.2.1.2.1 General

To be a valid input into the mapping, the GML application schema shall meet the requirements of Annex A.1 Conformance Class B. “Conformance of the XML Implementation of GML Application Schema”, and shall also conform to all of the following rules.

The GML application schema shall have and contain definitions for only one target namespace.

The GML application schema may import definitions from XML namespaces other than its target namespace.

A GML application schema consists of a set of one or more XML schema documents such that:

- the documents have unique names;
- the documents contain `xsd:include` elements for other schema documents with the same target namespace;
- one top level schema document for the GML application schema target namespace is not included by any other schema documents for the target namespace, but directly or indirectly includes all other schema documents for the target namespace, if any;
- the schema documents contain `xsd:import` elements for XML namespaces other than the target namespace, and for schema documents that contain definitions in those XML namespaces;
- all included and imported schema documents are accessible via the URI specified by the `schemaLocation` attribute on the `xsd:include` and `xsd:import` elements that reference them;
- a validating XML parser resolves all of the dependencies among the definitions contained in the set of schema documents;
- a validating XML parser validates the set of schema documents without error;
- a validating XML parser validates an XML instance document containing elements and attributes that represent all of the definitions from the target namespace of the GML application schema without error.

Documentation of the definitions contained in a GML application schema shall be stored in nested `xsd:annotation` and `xsd:documentation` elements within the schema definition elements.

The version of a GML application schema, if applicable, shall be contained in the `version` attribute of the `xsd:schema` element from the top level schema for its target namespace.

All global type and element names within a GML application schema shall be unique.

The GML application schema shall not define any elements with anonymous types.

The GML application schema shall not define any XML attributes or named groups.

Every complex type in a GML application schema shall either be a GML object type, GML feature type, a GML data type or a GML property type.

Complex types with simple content shall not be defined in the GML application schema.

The name of all types defined in a GML application schema shall end with the suffix “Type”.

A suffix “RestrictionType” in the name of a complex type shall only be used for an abstract type that derives by restriction and which is the base type of exactly one complex type that derives from this type by extension and has the same name as the restricted type except that “RestrictionType” is replaced by “Type”.

A suffix “PropertyType” in the name of a complex type shall only be used for an instantiable type that follows the pattern for by-reference-or-value property types of GML. A complex type (GML object type or GML feature type) with the same name shall exist that has “PropertyType” is replaced by “Type”.

A suffix “PropertyByValueType” in the name of a complex type shall only be used for an instantiable type that follows the pattern for by-value property types of GML. A complex type (GML data type, GML object type or GML feature type) with the same name shall exist that has “PropertyByValueType” is replaced by “Type”.

NOTE These rules severely restrict the possible forms of GML application schemas. It is possible that in the future more complex roundtrip mapping rules may be supported.

#### F.2.1.2.2 GML Object Types including GML Feature Types

Each GML object type defined in a GML application schema shall have a content model that directly or indirectly derives from `gml:AbstractGMLType` and shall have a `gml:id` attribute.

Each GML object type of a particular kind defined in a GML application schema shall derive from the most specialized GML object type from the “`http://www.opengis.net/gml`” namespace of a similar kind (with matching semantics) that could possibly be used to define its content model. So GML object types defined in a GML application schema to represent geographic features (GML feature types) shall derive from `gml:AbstractFeatureType` instead of from `gml:AbstractGMLType`, GML object types defined in a GML application schema to represent geometric points shall derive from `gml:PointType` instead of from `gml:AbstractGeometryType`, etc.

GML object types defined in the GML application schema that derive from GML object types outside of the target namespace shall derive directly only from one of the following GML object types from the GML namespace:

- `gml:AbstractGMLType`
- `gml:AbstractGeometryType`
- `gml:PointType`
- `gml:AbstractCurveType`
- `gml:AbstractSurfaceType`
- `gml:AbstractSolidType`
- `gml:CurveType`
- `gml:OrientableCurveType`
- `gml:LineStringType`
- `gml:AbstractCurveSegmentType`
- `gml:SurfaceType`
- `gml:OrientableSurfaceType`
- `gml:PolygonType`
- `gml:AbstractSurfacePatchType`
- `gml:SolidType`

- gml:CompositeCurveType
- gml:CompositeSurfaceType
- gml:CompositeSolidType
- gml:AbstractTopologyType
- gml:NodeType
- gml:EdgeType
- gml:FaceType
- gml:TopoSolidType
- gml:TopoCurveType
- gml:TopoSurfaceType
- gml:TopoVolumeType
- gml:TopoComplexType
- gml:TimeInstantType
- gml:TimePeriodType
- gml:TimeNodeType
- gml:TimeEdgeType
- gml:TimeTopologyComplexType

GML feature types defined in the GML application schema that derive from GML object types outside of the target namespace shall derive directly only from one of the following GML object types from the GML namespace:

- gml:AbstractFeatureType
- gml:AbstractFeatureCollectionType

The schema definitions of abstract GML object types shall contain the attribute “abstract” with the value “true”.

The name of abstract GML object types shall begin with the prefix “Abstract”.

The schema definitions of GML object types for which no subtypes may be defined shall contain the attribute “final” with the value “all”.

The properties of the GML object type shall be specified in a xsd:sequence element.

#### **F.2.1.2.3 Global Elements for GML Object Types**

One global XML element shall be defined for every GML object type defined in a GML application schema.

The name of this element shall be the name of the GML object type without the “Type”-suffix. If the type is abstract, the name prefix “Abstract” shall be replaced by an underscore (“\_”).

The element shall have a substitutionGroup attribute whose value is the name of a global XML element whose type is the base type of the GML object type.

#### **F.2.1.2.4 Default property types for GML Object Types**

A default GML property type may be defined in a GML application schema for every GML object type defined in that GML application schema.

The GML property type shall either inherit directly or indirectly from gml:AssociationType or gml:ReferenceType, or it shall be defined according to 7.5.3 “standard pattern for property declarations”.

The name of this property type shall be the name of the GML object type with the “Type”-suffix replaced by “PropertyType”.

If no default property type is specified for a GML object type, an application schema shall use gml:ReferenceType as the default property type of the GML object type.

#### **F.2.1.2.5 By-value property types for GML Object Types**

A default GML property type for by-value properties may be defined in a GML application schema for every GML object type defined in that GML application schema.

The GML property type shall either inherit directly or indirectly from gml:AssociationType, or it shall be defined according to 7.5.3 “standard pattern for property declarations”. The use of the gml:AssociationAttributeGroup is prohibited in such properties.

The name of this property type shall be the name of the GML object type with the “Type”-suffix replaced by “PropertyByValueType”.

If no default property type for by-value properties is specified for a GML object type, an application schema shall use gml:AssociationType as the default property type for by-value properties of the GML object type.

#### **F.2.1.2.6 GML Data Types including GML Union Types**

A complex type defined in a GML application schema that does not directly or indirectly derive from gml:AbstractGMLType is called a GML data type.

The properties of the GML data type shall take one of the following forms:

The content model of the complex type shall not include a gml:id attribute.

- The properties of the complex type as well as the properties of all of its base types are specified in a xsd:sequence element with minOccurs and maxOccurs values of “1”.
- The GML data type is not derived from any base type. In this case, the properties may be specified in either a single xsd:sequence element with minOccurs and maxOccurs values of “1” or a single xsd:choice element with minOccurs and maxOccurs values of “1”.

#### **F.2.1.2.7 Default property types for GML Data Types**

A default GML property type for by-value properties may be defined in a GML application schema for every GML data type defined in that GML application schema.

The GML property type shall either inherit directly or indirectly from gml:AssociationType, or it shall be defined according to 7.5.3 “standard pattern for property declarations”. The use of the gml:AssociationAttributeGroup is prohibited in such properties.

The name of this property type shall be the name of the GML data type with the “Type”-suffix replaced by “PropertyByValueType”.

If no default property type for by-value properties is specified for a GML data type, an application schema shall use `gml:AssociationType` as the default property type for by-value properties of the GML data type.

#### **F.2.1.2.8 Enumerations**

A simple type defined in a GML application schema that is a restriction of `xsd:string` using only the `xsd:enumeration` facet is called an enumeration.

#### **F.2.1.2.9 Code lists**

A simple type defined in a GML application schema that is a union of an enumeration and a simple type that is a restriction of `xsd:string` using only one `xsd:pattern` facet with the value “`other: \w{2,}`” is called a code list.

Enumeration values may be qualified with an `appInfo` annotation (source “`urn:x-gml:codelistValue`”) specifying that the enumeration value is the code value of another enumeration value; the associated enumeration value is given as the text value of the `appInfo` element.

#### **F.2.1.2.10 Global Elements for GML Data Types, enumerations and code lists**

No global XML element shall be defined for GML data types, enumerations or code lists defined in a GML application schema.

#### **F.2.1.2.11 Predefined basic types**

The simple types from the XML Schema and GML namespace listed in the left hand column of Table 22 may be used in the GML application schema. All other simple types from these namespaces shall not be used in a GML application schema.

#### **F.2.1.2.12 GML properties**

Every property of a GML object type (except properties defined in the GML namespace) or of a GML data type shall – with one exception – be represented by a single, locally defined `xsd:element`. Locally defined means that the name and type of the element shall be given explicitly in the element declaration (no references to global XML elements). The element may carry `minOccurs` and `maxOccurs` values. The name of this element shall be the name of the property, the type shall be either a simple type or a property type.

The exception are elements that are substitutable for `gml:featureMember`. These property elements shall be defined as global elements and with a substitution group attribute value of “`gml:featureMember`”. These elements shall only be referenced from GML feature types derived by restriction directly from `gml:AbstractFeatureCollectionType`. The name of such elements shall end with the name of the global element of the target GML feature type.

#### **F.2.1.2.13 Schematron Constraints**

All Schematron constraints are ignored.

#### **F.2.1.2.14 Other information**

All other information in the GML application schema is not used in the encoding rules and is ignored.

### **F.2.1.3 Character repertoire and languages**

The character encoding used for the schemas determines the available character repertoire.

#### F.2.1.4 Exchange metadata

Exchange metadata can be specified for every Feature or Feature Collection in a GML instance document<sup>10</sup>. No specific schema for the exchange metadata is added to the GML application schema.

#### F.2.1.5 Dataset and object identification

Unique gml:id identifiers according to 7.5.6.5 and XML's ID mechanism shall be used to identify GML objects.

#### F.2.1.6 Update mechanism

No explicit update mechanism shall be defined for the feature types defined in a GML application schema. It is assumed that other mechanisms are used to update an instance model data store.

#### F.2.1.7 Input data structure

The schema for the input data structure is defined by the XML Schema 1.0 Part 1: Structures and Part2: Datatypes W3C Recommendations, and the Rules for GML Application Schemas (see clause 23).

### F.2.2 Output data structure

See ISO DIS 19118 A.3 for a description of the output data structure.

### F.2.3 Conversion rules

#### F.2.3.1 General concepts

The schema conversion rules defined in the following clauses describe the mapping from a GML application schema that follows the guidelines described in F.2.1 to a UML application schema that conforms to the rules defined in ISO DIS 19109 and ISO PDTS 19103, using the encoding rules of of ISO DIS 19118 Annex A and in particular the generic instance model described in section A.3. These rules are also based on the current rules for the GML model and syntax as described in clauses 7 to 23 (especially clause 7).

The schema conversion rules map definitions from a (set of) valid GML application schema documents (XSDs) to a set of UML packages. A top level package with the stereotype <<Application Schema>> is created to contain all the other packages in this set. By default, one package is created in this set for each XSD in the GML application schema, including those directly or indirectly imported from XML namespaces other than the target namespace for the GML application schema, except for XSDs for the GML namespaces. The top level package owns directly or indirectly all UML model elements mapped from object types in the GML application schema.

It is allowed to arrange the definitions of GML application schema in a different package structure as long as the top level package keeps its name and stereotype and all the model elements still belong directly or indirectly to this package.

The type and element declarations in the GML application schema are mapped to class definitions in the UML application schema, so that element structures in the GML XML document can be mapped to corresponding objects in the instance model.

The UML model shall contain the normative packages of the ISO 19100 Harmonized Model or a strict profile of this model.

---

<sup>10</sup> By using the "gml:metaDataProperty" element and, for example, the ISO WD 19139 XML Schema encoding of ISO 19115:2003.

The UML model shall contain the UML package of all other GML application schemas imported by the GML application schema.

The following table gives an overview, full details of the mapping are specified in the subsequent clauses:

**Table 20 – Schema encoding overview**

Table: GML → UML Application Schema Overview	
GML Application Schema	UML Application Schema
GML application schema	Package <<ApplicationSchema>>
GML schema document {name} XSD	Package named {name}
Object and property type and global element for any object type that is a direct or indirect extension of gml:AbstractFeatureType	Class with stereotype <<Featruetype>>
Object and property type and global element for any object type that is a direct or indirect extension of gml:AbstractGMLType, other than those that extend gml:AbstractFeatureType	Class with stereotype <<ObjectType>>
Data and property type and global element for any object type that is not a direct or indirect extension of AbstractGMLType and whose content model is a sequence of properties	Class with stereotype <<DataType>>
Restriction of xsd:string with enumeration values	Class with stereotype <<Enumeration>>
Union of an enumeration and a pattern	Class with stereotype <<CodeList>>
Data and property type and global element for any object type that is not a direct or indirect extension of AbstractGMLType and whose content model is a choice of properties	Class with stereotype <<Union>>
Local xsd:element of a simpleType or a complexType with simpleContent or a type that does not directly or indirectly inherit from gml:AbstractGMLType	UML Attribute
Local xsd:element of a type that contains gml:AssociationAttributeGroup	UML Association Role
Schematron constraints	Not encoded

The multiplicity of attributes and association roles is derived from the minOccurs and maxOccurs attributes in local xsd:element declarations.

### F.2.3.2 GML Schema Documents

A top level package with the stereotype <<Application Schema>> is created to contain all the other packages generated for the GML application schema.

- The “xmlNamespace” and “xmlNamespaceAbbreviation” tagged values are applied to the <<ApplicationSchema>> package with corresponding values for the target namespace of the GML application schema

EXAMPLE “http://www.myorg.com/myns” and “myns”

- The “version” tagged value is applied to the <<ApplicationSchema>> package with the default value of “1.0”. If the “version” attribute of the xsd:schema element of the top level schema document for the GML application schema exists and contains a non-empty value, its value replaces the default tagged value.

By default, one UML package is generated for each input schema document in the GML application schema, including those directly or indirectly imported from XML namespaces other than the target namespace of the GML application schema – except for XML Schema documents from the GML namespaces. Alternatively, a single XML Schema document may also be split into several UML packages.

The packages are generated in the <<ApplicationSchema>> package for the GML application schema with names that correspond to the names of the input schema documents.

The xsd:include and xsd:import statements in each input schema document are used to determine and set the dependencies of the packages generated in the <<Application Schema>> package.

### F.2.3.3 GML Object Types

Every GML object type shall be mapped to a UML class.

If the object type directly or indirectly derives from gml:AbstractFeatureType, the stereotype of the class shall be <<FeatureType>>, otherwise the stereotype shall be <<ObjectType>>.

The name of the class shall be the same as the name of the global element of the GML object type.

The class shall be abstract, if and only if the GML object type is abstract.

If the GML object type is derived from another GML object type, then the class inherits from the corresponding superclass. If the base type is defined in the GML application schema or another imported GML application schema, then the superclass is the class corresponding to this GML object type. If the base type is defined in the GML namespace, then the superclass is determined by Table 21.

Table 21

GML object type	ISO 19100 class
gml:AbstractGeometryType	GM_Object
gml:AbstractGeometricPrimitiveType	GM_Primitive
gml:PointType	GM_Point
gml:AbstractCurveType	GM_Curve
gml:AbstractSurfaceType	GM_Surface
gml:AbstractSolidType	GM_Solid
gml:PointType	GM_CompositePoint
gml:CompositeCurveType	GM_CompositeCurve
gml:CompositeSurfaceType	GM_CompositeSurface

gml:CompositeSolidType	GM_CompositeSolid
gml:GeometricComplexType	GM_Complex
gml:MultiGeometryType	GM_Aggregate
gml:MultiPointType	GM_MultiPoint
gml:MultiCurveType	GM_MultiCurve
gml:MultiSurfaceType	GM_MultiSurface
gml:MultiSolidType	GM_MultiSolid
gml:MultiGeometryType	GM_MultiPrimitive
gml:DirectedNodeType	TP_Node
gml:DirectedEdgeType	TP_Edge
gml:DirectedFaceType	TP_Face
gml:DirectedTopoSolidType	TP_Solid
gml:DirectedNodeType	TP_DirectedNode
gml:DirectedEdgeType	TP_DirectedEdge
gml:DirectedFaceType	TP_DirectedFace
gml:DirectedTopoSolidType	TP_DirectedSolid
gml:TopoComplexType	TP_Complex
gml:TimeInstantType	TM_Instant
gml:TimePeriodType	TM_Period
gml:TimeTopologyComplexType	TM_TopologicalComplex
gml:TimeNodeType	TM_Node
gml:TimeEdgeType	TM_Edge

The GML properties of the GML object type shall be mapped to attributes and association roles as described in clause F.2.3.9.

#### F.2.3.4 GML Object Types (imported from the GML schemas)

The complex types from the GML namespace listed in the left hand column of Table 21 shall be mapped to the predefined UML classes from the ISO 19100 profile of GML in the right hand column of the table.

#### F.2.3.5 Basic Types

The simple types from the XML Schema and GML namespace shown in the left hand column of Table 22 shall be mapped to the predefined UML classes from the ISO 19100 profile of GML in the right hand column of the table.

Table 22

XML type	UML class
xsd:string	CharacterString
xsd:boolean	Boolean

xsd:float	Real
xsd:double	Real (Default), Decimal or Number
xsd:decimal	Decimal
xsd:date	Date
xsd:time	Time
xsd:dateTime	DateTime
xsd:integer	Integer
gml:VectorType	Vector
gml:CodeType	GenericName (default), LocalName oder ScopeName
gml:LengthType	Length
gml:AngleType	Angle
gml:SpeedType	Velocity
gml:ScaleType	Scale
gml:AreaType	Area
gml:VolumeType	Volume
gml:MeasureType	Measure
xsd:nonPositiveInteger	Integer
xsd:negativeInteger	Integer
xsd:nonNegativeInteger	Integer
xsd:positiveInteger	Integer

### F.2.3.6 GML Data Types

Every GML data type shall be mapped to a UML class. The name of the class shall be the same as the name of the complex type without the "Type"-suffix.

If the GML data type is derived from another GML data type (base type), then the class inherits from the corresponding superclass.

If the properties of the GML data type are embedded in a xsd:sequence element, the stereotype of the class shall be <<DataType>>, if they are embedded in a xsd:choice element, the stereotype of the class shall be set to <<Union>>.

The GML properties of the GML object type shall be mapped to attributes and association roles as described in clause F.2.3.9.

### F.2.3.7 Enumerations

A simple type defined on the GML application schema as a restriction of xsd:string with enumeration values shall be mapped to a class with the <<Enumeration>> stereotype in the UML application schema.

The name of the class shall be the name of the simple type.

Every xsd:enumeration facet without an xsd:appInfo annotation with a source attribute "urn:x-gml:odelistValue" shall be mapped to an UML attribute with the value as the attribute name.

Every `xsd:enumeration` facet with an `xsd:appInfo` annotation with a source attribute “urn:x-gml:codelistValue” shall be mapped to an initial value of the UML attribute with the same name as the value of the `appInfo` element. If no such UML attribute exists in the class, the facet shall be ignored.

### F.2.3.8 Code lists

A simple type defined in the GML application schema as a union of a `xsd:pattern` restriction with the value “other:\w{2,}” and an enumeration shall be mapped to a class with the stereotype <<CodeList>> in the UML application schema.

The name of the class shall be the name of the simple type.

Every `xsd:enumeration` facet of the enumeration without an `xsd:appInfo` annotation with a source attribute “urn:x-gml:codelistValue” shall be mapped to an UML attribute with the value as the attribute name.

Every `xsd:enumeration` facet of the enumeration with an `xsd:appInfo` annotation with a source attribute “urn:x-gml:codelistValue” shall be mapped to an initial value of the UML attribute with the same name as the value of the `appInfo` element. If no such UML attribute exists in the class, the facet shall be ignored.

### F.2.3.9 GML properties

If the type of a property element

- is a simple type or the property type of GML data type, the property shall be mapped to an UML attribute with the corresponding type as the data type
- is a by-value property type of a GML object type, the property shall be mapped to an UML association role of a UML composition to the class representing the target GML object type
- is a by-reference-or-value property type of a GML object type, the property shall be mapped to an UML association role of a UML association to the class representing the target GML object type
- is a by-reference property type of a GML object type, the property shall be mapped to an UML association role of a UML association to the class representing the target GML object type where the target GML object type shall be determined from the embedded `xsd:appInfo` annotation with a source attribute value “urn:x-gml:targetElement” specifying the qualified element name of the target type).

The name of the UML attribute or association role shall be the name of the GML property element.

The multiplicity of the UML attribute or association role shall be derived from the `minOccurs` and `maxOccurs` value of the GML property.

If the property element has an `xsd:appInfo` annotation with a source attribute value “urn:x-gml:reverseProperty” embedded, then the association role shall be defined as part of the association between the two classes where the other association role has a name equal to the value of the `xsd:appInfo` element.

### F.2.3.10 Documentation

XML Schema `xsd:annotation/xsd:documentation` elements in GML application schemas are mapped to “documentation” tagged values in the UML application schema.

## Annex G (Informative)

### Guidelines for Subsetting GML Schemas

#### G.1 General

An automated approach is recommended for subsetting GML schemas. This annex contains an informative XSLT reference implementation of a GML schema subset tool. The tool consists of three XSLT stylesheets, the three stylesheets are show in clauses G.2, G.3 and G.4 below.

To create a GML subset schema using this tool:

1. Transform gml.xsd using depends.xslt and an XSLT processor to produce gml.dep, e.g. using Xalan by

```
$ java org.apache.xalan.xslt.Process -IN ../base/gml.xsd -XSL depends.xslt -OUT gml.dep
```

2. If the XSLT processor you are using cannot pass parameters to a stylesheet being processed, edit gmlSubset.xslt, and change the “wanted” parameter to contain a comma separated list (with a trailing comma) of the namespace-qualified global types and elements you want in your GML subset schema. For example, change

```
<xsl:param name="wanted">,</xsl:param>
```

to

```
<xsl:param name="wanted">gml:featureProperty,gml:lineStringProperty,gml:polygonProperty,</xsl:param>
```

3. Transform gml.dep using gmlSubset.xslt, a parameter named “wanted” set to a comma separated list (with a trailing comma) of the namespace qualified global types and elements you want in your GML subset schema, and an XSLT processor to produce gmlSubset.xsd, which will contain the global types and elements specified in the “wanted” parameter and all of the global types and elements on which they directly or indirectly use.
4. If your “wanted” list did not include or depend on any elements or types from the namespaces named “smil20” or smil20lang, you may wish to edit the generated schema to remove the following namespace definitions from the schema element:

```
xmlns:smil20="http://www.w3.org/2001/SMIL20/"
```

```
xmlns:smil20lang="http://www.w3.org/2001/SMIL20/Language"
```

```
xmlns:x="http://www.w3.org/XML/1998/namespace"
```

5. The generated gmlSubset.xsd will include imports for the namespaces named “xlink”, “smil20” and “smil20lang” if your “wanted” list included or depended on any elements or types from the corresponding namespaces. Otherwise, it is a stand-alone GML subset schema that conforms to the requirements for GML profiles.

## G.2 depends.xslt

```

<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:xlink="http://www.w3.org/1999/xlink">
  <!-- =====
  This stylesheet is designed to be used on gml.xsd to produce gml.dep
  for use by the gml schema subset utility gmlSubset.xslt to produce a specialized
  gmlSubset.xsd that contains only the specified types and elements, and the types
  and elements on which they depend.
  ===== -->
